When, by a process of strict reasoning from certain fundamental and well-established principles we arrive at an expression for the amount of radiant energy emanating from a hot body and existing in a unit volume of the ether, we have two very astonishing results. In the first place, experiment shows that the total amount of energy existing in a unit volume of the ether is distributed among the rays of different wave lengths in such a way as to be a maximum for a certain wave length (depending on the temperature) while our theoretically obtained expression does not admit of a maximum. In the second place, according to our formula the total quantity of energy would be infinite, a result which cannot be admitted. Planck, the great German physicist, was accordingly led to consider a radiating body as made up of a number of small bodies called resonators, the energy of which varies in a discontinuous manner. The total energy possessed by any resonator (which might be an atom of sodium, for example) at any time must be a whole multiple of some fundamental unit of energy. The atom of energy in any case depends upon the frequency of oscillation of the resonator and is, indeed, simply proportional to it. This very strange theory enables a formula to be obtained for the quantity of energy *per unit volume of the* ether due to radiation which agrees with experiment, possesses a maximum, and gives a finite value for the total quantity of energy. It was discussed before a distinguished audience at the last meeting of the British Association and promises to be of great importance in many branches of scientific investigation.

A Plan for Safeguarding Miners

[illegible] Editor of the Scientific American:

[illegible] the number of lives yearly exacted in coal [illegible] from explosions, black-damp, roof falls, flood- [illegible] passageways in mines, and for which no adequate [illegible] has yet been devised to counteract by allowing [illegible] an opportunity to escape, the problem leads me [illegible] submit for your consideration a plan by which in [illegible] all cases of mine disaster the loss of life could [illegible]. The plan, as any practical man can see, [illegible] entail on mining companies a large additional [illegible], but for humanity's sake mining companies [illegible] been compelled by legislation to adopt equipment [illegible] the safeguarding and welfare of mine workers.

The idea is as follows:

By referring to Fig. 1, the wall of one side of the [illegible] passage should be undercut or sloped as shown in sketch to receive a pipe or tube twenty-four inches in diameter by one quarter of an inch thick, riveted and calked watertight. This emergency tube to extend throughout the main passages of the mine, this tube to have watertight doors placed every hundred feet apart, and where there is a vertical shaft, grab irons or steps be riveted on inside of vertical portion of tube to top of mine shaft.

The operation or use of such a tube would be as follows:

In the event of a "cave-in," or the roof collapsing, cutting miners off from the outside world, and bringing them face to face with death from starvation or thirst, the miners would enter pipe or tube through manhole nearest to them and get through or past the "cave-in" or fall, and return to daylight, home and life without having heart-rending accounts published of men buried alive. In fact, operations could be carried on the same as usual while the "cave-in" was being removed.

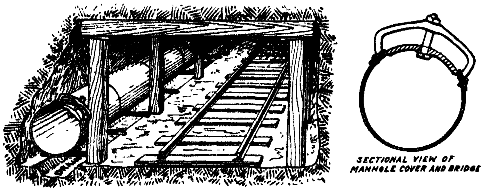
In the event of a mine explosion, provided there was no fire vomiting from mouth of mine, the miner could escape the danger from "black-damp," or the deadly gas which follows a mine explosion. Of course, these manholes and doors should be closed from the inside as soon as the last man has entered. The fan blast system in use in mines could be arranged so as to feed the emergency tube constantly with fresh air. This emergency tube could extend to top of both the down and up shafts, allowing escape from a mine either way.

In the event of a mine getting flooded with this means of escape at hand no lives would be lost, for men with nerve enough to work in a mine, would possess sufficient nerve to take advantage of this means of escape to save their own lives by entering the tube which would lead them to the world above, their families and complete safety.

I hope for humanity's sake this idea will be made use of. I do not know of any channel more suited to exploit this suggestion than the columns of the Scientific American, which reaches men engaged in the great work of making our industries safer and more attractive to the worker.

The initial cost of such an emergency tube should not be any more prohibitive than the cost of hoisting engines, pumps, fans, or any other kind of equipment necessary for the mining of coal. I feel assured that such an appliance would decrease by a large percentage the number of lives annually lost and chronicled as imprisoned, overcome by black-damp, or drowned by not having a means of escape.

Detroit, Mich. George W. Bowie.



An emergency tube for miners.

Philippine Industries

To the Editor of the Scientific American:

Our attention has been invited to certain articles appearing in the Scientific American from time to time concerning the industrial situation in the Philippine Islands. Particular reference is made to an article appearing recently in which the extension of hat making in the Philippine Islands was discussed. We believe it well to bring to your attention some first hand information on what is being done along industrial lines in the Philippine Islands, and to refer you to certain publications of the Bureau of Education on industrial subjects.

The Bureau of Education maintains a very complete system of industrial instruction in the Philippine public schools. Special attention has for some time been given to basketry, loom weaving, lace making and embroidery, wood working, iron working, and domestic science and sanitation. The industrial system has gradually been extended until at present 98 per cent of the pupils in the Philippine public schools receive some form of industrial training. Most of those not receiving industrial instruction are in the secondary grades.

The Bureau of Education has published for nearly two years an industrial magazine under the title, *The Philippine Craftsman*. This magazine was founded for the purpose of encouraging industrial instruction and making available to all interested parties the results of the industrial work in different sections of the islands and the plans for further extension of industrial instruction into the public schools. It encourages the development of native arts and the introduction of such as will prove of economic value to the people.

Manila, P. I. C. H. Mayer, *Acting Director.*

That Coin Problem

To the Editor of the Scientific American:

The following is my answer to the United States coin problem, published in the Scientific American of February 7th:

100	1-cent	$1.00
9	5-cent	.45
13	10-cent	1.30
13	25-cent	3.25
13	50-cent	6.50
13	2.50 gold	32 50
13	5.00 gold	65.00
13	10.00 gold	130.00
13	20.00 gold	260 00
200 coins.		$500.00

Theodore L. DeLand, *Shipping Clerk.*
United States Mint, Philadelphia, Pa.

To the Editor of the Scientific American:

In your issue of February 7th, on page 117, under the heading "A Problem in United States Coins," the question is asked, "How can 200 coins of the United States (present coinage) be so divided as to total $500? Every coin to be used at least once." Here is one answer:

60	.01	$0 60
6	.05	.30
6	.10	.60
6	.25	1.50
14	.50	7.00
68	2.50	170 00
28	5.00	140.00
6	10.00	60 00
6	20.00	120 00
200		$500 00

Possibly there are other combinations, or perhaps the question is not complete. F. M. Greene.

Minneapolis, Minn.

[We can publish no more letters on this subject.—Editor.]

A Miniature Volcano

To the Editor of the Scientific American:

Recently I saw a very interesting imitation of a volcano, and as it may be of interest to your readers, I shall describe it.

A slag pot, containing about four tons of slag from a lead blast furnace, had been set on the dump to settle before being tapped. The top was covered with a crust of slag which would take a good blow with a sledge to break. In one place near the center was a hole where the slag was still red hot and molten. Every little while flames came up from this and some gas was given off, throwing the slag up around the edges till a mound was formed around the hole. Every minute or so a flame and some smoke shot up and some slag overflowed the top and ran down the sides till it cooled, thus building the mound higher. These eruptions continued about one or two minutes apart till the mound was about six inches high. Every one consisted of flame, smoke, a flow of lava, and then a period of quiet. This continued till the pot was tapped, perhaps twenty minutes, when the withdrawal of the slag stopped the eruptions.

A mixture of adobe and water had been put in the pot before the slag had been tapped into it, to allow the shell to come out easily, and probably a reaction between this and the hot slag caused the phenomena.

The tapper at the dump informed me that he had seen a number of these little volcanoes, but they were by no means common. Edward P. Chapman.

Pueblo, Colo.

The First to Signal Through Space

To the Editor of the Scientific American:

In a notice of John Walker Wilkins, in Scientific American of January 31st, it is stated that he was "the first man in the world to transmit telegraphic signals through space." From data in the notice, it was not earlier than 1845 or 1846 that he did this, three or four years subsequent to the time that Joseph Henry, American physicist, had "traced the influence of induction to surprising distances, magnetizing needles in the lower story of a house through several intervening floors by means of electrical discharges in the upper story, and also by the secondary current in a wire 220 feet distant from the wire of the primary current." (Enc. Brit., 9th ed., vol. xi, page 675.) In connection with these experiments he discovered the oscillatory nature of the electric discharge. I know of no earlier signaling through space by the use of electric currents.

Carlisle, Pa. I. Thornton Osmond

The "Nevada" and "Queen Elizabeth" Compared

To the Editor of the Scientific American:

I noticed in one of your recent publications remarks by Mr. C. P. Slosson, San Francisco: the comparison of the British "Queen Elizabeth" and United States 'Nevada;" also remarks on speed of British battle-cruisers. I also noticed your answers to said remarks. Now if you will permit me, I would like to say a few words. In the first place, I may say it has always been a very great pleasure to me to read your valued paper. A Britisher naturally likes fair play, and I am sure the Scientific American puts a thing fairly and squarely before the public. Of course, in making a comparison it is only fair to compare contemporary ships. Now, take into consideration the four great events or essentials in a warship, viz., speed, radius of action, gun power, and defensive armor. Of course, the British ship has the advantage, a great advantage, in speed. In radius of action, as both ships are to use oil fuel exclusively, and as reliable data are not at hand, I cannot say for sure as to which has the advantage on that point. In gun power we have ten 14-inch guns with 1,400-pound shell, and 2,600 foot-seconds, energy, 65,008 foot-tons on the "Nevada." Eight 15-inch guns with 1,950-pound shell, 2,500 foot-seconds; energy, 84,510 foot tons on the "Queen Elizabeth." Here we see the British ship, although carrying fewer guns, throws a heavier weight of metal at a discharge with a greater energy, which would be more effective at long range. The weight of the American gun is 63 1 tons. The weight of the British gun is 96 tons; both 45 calibers long. In defensive armor or qualities of defense the principal interest in the "Nevada" class is their great defensive power and the armor has been, or will be, so disposed to a greater advantage than on any ship hitherto built, at least from the American standpoint. From a British standpoint the armor is so disposed on the "Queen Elizabeth" to the greatest possible advantage; the armor on both is about the same maximum thickness, so in recapitulation we have "Queen Elizabeth," greater speed; "Queen Elizabeth," greater gun power, 'Queen Elizabeth," at least equal defensive power, "Queen Elizabeth," questionable radius of action. You cannot put a quart of power in a pint of displacement, and as both displacements are about the same, for the displacement given of British ships are their displacements when in commission with full load of stores, ammunition, etc., but with normal coal capacity, I take it that British designers have turned out the better ship, more especially as the cost per ton is less in the case of British ships. Take for instance contemporary ships "Neptune" and "Delaware." The British "Neptune" works out $418 per ton. The United States "Delaware" works out about $450 per ton. The British ship "Lion" worked out at $382 per ton. W. R. Shute.

Woodstock, Ontario.

Roadside Signs, each containing a single catchy sentence in large type, are proving effective in warning against fires on western forests. They give the essentials and tell the importance of protection against forest fires.

First water discharging through the Gatun spillway after the lake has been filled to the full 85-foot level.

Navigating Lights for the Panama Canal

How Ships Will be Guided Through the Canal by Night

THE lighting equipment of the Panama Canal has been planned with the same care and skill that has been displayed in the other parts of this monumental work. Through Gatun Lake and at the approaches the sides of the channel will be marked by gas buoys, and except in Culebra Cut, a set of flashing range lights will be placed at each end of the successive tangents. The sailing lines, as indicated by the range lights, will be sufficiently wide apart to enable the largest vessels to pass one another in safety.

In Culebra Cut, the banks are so close together as to make the use of range lights impracticable. In this part of the canal, three lighted beacons will be placed at each angle or turning point in the cut and between these there will be intermediate lights in pairs on each side of the canal. While these lights are deemed ample for safe navigation, it will not enable travelers to see very much of that famous locality should their ship pass through on a dark night. All the beacon and range light towers along the canal will be of molded concrete.

The locks, however, will be brilliantly illuminated by electricity. On the walls of the locks there are molded concrete lamp standards, carrying hoods of concrete in which are mounted large, 400-watt, tungsten bulbs. The hoods will be so arranged as to throw the light on the coping of the lock, and the water chamber, but will screen the lights from the axis of the canal. If these brilliant lights were not shaded, the pilots on approaching vessels would be so blinded as to hinder them from observing the range and signal lights. Excepting the locks, acetylene will be used exclusively for lighting the canal both in the towers and on the buoys. These lights will be automatic in the sense that they will require absolutely no attention for a period of from four to seven months after they have been once started. At the end of that time their supply of acetylene is replenished and they are good for another period. This system, known as the A. G. A. (American Gas Accumulator Company) system, was first introduced in this country in 1908, and since then has been installed in over three hundred important light stations on our coast.

This system has perhaps its highest development in the gas buoy. The lighted buoy is considered one of the most important and reliable aids to navigation invented in recent years. The lights of those installed by the lighthouse authorities on various stations on the coast, are plainly visible from six to fifteen miles and will burn for long periods up to a year or more without any attention. The buoys along the canal will be equipped with sixth order lights, and the gas supply in each beacon is designed to last from three to seven months, the time depending upon the characteristic of the light. These buoys will be of the same standard type used generally by the lighthouse service. Its structure is indicated in Fig. 1, and it consists of a cylindrical floating steel body carrying on its top a pyramidal steel frame which supports a light and lens fifteen feet above the water level. To the bottom of the body is attached a steel tube carrying a counterweight, and this tube is made detachable from the buoy body to facilitate transportation. The buoy will be moored on its station by heavy chain and concrete sinkers. The corrosive effect of the waters of Gatun Lake, due to decaying vegetable matter, is very pronounced, and hence the metal surfaces will be given a special protective coating.

The body is eight feet in diameter and has dished heads, and in the periphery of the upper one are four pockets for the reception of the cylinders containing acetylene, technically known as "accumulators." The gas from the four accumulators passes out through a collecting manifold and thence up a feed pipe secured to one of the upright frame pieces to the lantern.

The acetylene in the accumulators is stored according to the process invented jointly by three Frenchmen, Claude, Hess and Fouche. This gas, at ordinary atmospheric temperature, is very unstable under a pressure of more than two atmospheres, as it readily breaks down into carbon and free hydrogen under slight shocks, and this is usually accompanied by a violent explosion. When stored by the process mentioned, it is practically safe and harmless. The cylinders are first filled with an inert porous mass having a porosity of eighty per cent, and half the porous space is then filled with acetone a hydrocarbon liquid which boils at 56 deg. Cent. The acetylene is then forced into the cylinders under heavy pressure. The acetone readily absorbs acetylene at atmospheric pressure and under a pressure of 150 pounds it will absorb over one hundred times its volume. The liquid acetone expands in absorbing acetylene and shrinks again to its original volume when the gas is exhausted. The purpose of the porous filler is to prevent the accumulation of compressed gas in the upper part of the accumulator when it is nearing exhaustion. A full description of this method of storing acetylene will be found in the SCIENTIFIC AMERICAN for May 6th, 1911, page 453. A gas plant will be established at Balboa, where the accumulators will be recharged when exhausted, and the acetone which may be carried out with the acetylene will be replaced.

All the canal buoys will have flashing lights possessing several interesting and novel features. The mechanism, as will be seen from Fig. 2, consists of three parts: the pressure reducer or governor, the flasher and the burner. The high-pressure gas from the accumulators goes first to the governor which operates to feed the gas at a constand low-pressure to the flasher. Two sections of the simplest form of flasher are shown in Figs. 3 and 4. It is the invention of Gustaf Dalen, a Swedish engineer. This consists of a heavy cup-shaped casing closed at the top by a leather diaphragm. In the side wall is a gas inlet for the low-pressure gas from the governor and a gas outlet leading to the burner. The inlet is always open, but the outlet to the burner is controlled by a pivoted valve which opens at stated periods, to permit gas to escape to the burner to produce the flash. In order that the valve may move at high speed, the valve seat around the outlet is made one pole of a permanent magnet, and the valve plate is acted upon by a spring to hold it in closed position. The valve plate is connected by an adjustable loose motion device with the diaphragm. When the valve is closed, gas accumulates in the casing under the diaphragm until its pressure is sufficient to overcome the force of the spring and the magnetic attraction of the valve seat. Then the valve opens with a jump and the gas escapes to the burner where it is ignited by a constant burning pilot flame fed directly from the governor. The escape of gas permits the diaphragm to fall and the valve closes quickly. By this mechanism, the pressure of the gas at the burner is constant throughout the duration of the flash, which is a very important feature, as it enables a pilot to judge accurately the characteristics of the light. It is also economical, as it has been found that 55,000 separate and distinct flashes can be obtained from one cubic foot of acetylene. They may be adjusted to give light periods as small as one tenth of a second, but on the canal the minimum period will be three tenths of a second. To give the various lights individual characteristics, a more complex form of this flasher will be used which will produce successive flashes, followed by dark intervals. Although this apparatus is very delicate and capable of fine adjustment, still the parts are so well protected that the buoys can withstand the buffeting of the heaviest seas without derangement.

By an ingenious arrangement of glass prisms on the inside of the vertical bars of the lantern, the light will be so reflected as to prevent the bars from casting any shadow. This is important; for in the older types much of the light is obstructed by the bars and lost. Acetylene light, which is almost pure white like sunlight, has a great penetrating power in thick weather, and as it burns with a small and intensely bright flame, it is easily adjusted in the focus of the lens which facilitates a uniform spread of the light in all directions in a horizontal plane. The hood shown is of sheet copper and serves for ventilation and is so constructed as to make it impossible for wind or sea to extinguish the light.

This type of buoy has been placed on each lan-

The Problem of Our Navy

II.—Sea Power and Our Foreign Policies

By the Editor

WE have it on the authority of the greatest of all books of wisdom that "No man liveth to himself"; and what is true of the individual may be applied with ten-fold emphasis to the nation. Although ambition is one of the most compelling forces in the make-up of the average individual, there has always been a minority of men who would gladly forego the larger prizes if they might only pursue their plan of action well out on the edge of the maelstrom of life, and as far removed as possible from the hazards of its central vortex. Hence, the hermit of early times and the shy recluse of our own day.

History can afford instances, not a few, of states and nations which have exhibited, from the very day of their birth, a decided spirit of reserve, a wish, sincere, well reasoned out, and formulated as a definite principle of action, to work out their destiny in an attitude of international aloofness, even if it involved isolation.

To find a conspicuous example of this spirit it is not necessary to go beyond our own borders. When our fathers "brought forth a new nation, conceived in liberty and dedicated to the proposition that all men are free and equal," they warned this country against any "entangling alliances" with foreign powers. The young Republic, guarded and guided by a Constitution into which its noblest men had written its highest ideals, set itself to the task of realizing those ideals in the unhindered development of the country, vast in extent and rich in its natural resources, of which, by the sword, it had recently won acknowledged possession.

Set midway between the Occident and the Orient, separated by a barrier of three thousand miles of ocean from the one, and by five thousand miles of the little-known Pacific from the other, the new-born State believed that its problems lay, and would forever lie, strictly within its own borders, and that its national policies would always be purely domestic in character—that they would never broaden out into policies of an international scope.

And so, for a full century of its existence, the United States worked out its destiny along and within the lines laid down by its founders. In numbers, wealth, industry and commerce it grew amazingly, and if war came, it was a war of defense. The one definite policy that was pregnant with possibilities of European complications, the Monroe Doctrine, was adopted early in our history at the suggestion of Great Britain, whose fleet stood ready in those early years to enforce the doctrine should it be challenged. It is only in late years that the Monroe Doctrine has loomed up in all its portentous significance.

Hence, throughout the first century of our national existence, the armed forces of the country, both naval and military, were regarded and designed purely for purposes of defense; and it is significant of this spirit and of the purely national as distinguished from the international character of our policies, that our first three battleships, the "Oregon," "Massachusetts" and "Indiana" were officially designated as coast-defense battleships—they were not designed, nor were they qualified, for service in far-distant waters.

Then, in the midst of our self-engrossed and aloof national life, came the roar of the "Maine" explosion; and before our President could exhaust the last resources of diplomacy, the United States was at the death-grip with a European nation! The century-long day of our isolation was over. From that war we emerged a great world power, to find ourselves standing toe-to-toe with the naval and military giants, young and old, of Asia and Europe.

How many of the eighty millions of us, in 1898, realized that in reaching out a pacifying hand across the few miles of water dividing Key West from Cuba, we were commencing to move our frontiers out into the international ocean highways of the world, and that when, at the close of the war, the extension had ceased, those frontiers would have been pushed nigh a thousand miles eastward into the Atlantic, and westward some five thousand miles, even to the very doors of Asia.

Not for a moment did the nation regard the Spanish war as one of aggression; it was supposed to have been fought in the interests of humanity, and for the abatement of the horrors of the Cuban situation. If we remember rightly, the diplomatic intercourse, antecedent to the war, deplored the disturbing conditions "*on*" or "*near our borders.*" It was the propinquity of the trouble that brought it within our concern—had Cuba been off the coast of Spain, the rebellion might have been raging yet, so far as any protest from this country would have been concerned. But, in fact, though not with definite intent, this nation, in declaring war against Spain, abandoned a policy of isolation for one of commanding importance in the great-world politics!

It is for us, now, either to play the games with great-world weapons and on a great-world scale, or confess ourselves unequal to the task, let go what destiny thrust upon us and be subjected by the leading powers to that attitude of interested tolerance which obtained before the war took place. There is no middle course. In the Atlantic the struggle left us in possession of Porto Rico, with oversight of Cuba and the possession of Guantanamo Bay, one of the finest strategical bases in the West Indies. In the Pacific we emerged with full responsibility for the Philippine Islands and holding also Guam, a most valuable strategic base in the Mid-Pacific. Verily, we have given hostages to fortune.

It is extremely significant that the subsequent course of our foreign policies, so far from showing any disposition on the part of the Administration to deplore the conditions which had established us in a very strong strategic position in both the Atlantic and Pacific Oceans, has rather indicated that we were disposed to utilize that position to the fullest advantage. Stimulated by the successes of the Spanish war, we built up our navy, and particularly its first fighting line of battleships, so assiduously that within a single decade we had risen to the second place in naval strength. Vith a natural naval base at Guantanamo, giving us a commanding position in the Caribbean, we took in hand the [illegible] possible task of cutting a canal from the [illegible] Pacific at Panama. For certain [illegible] the treaty rights of Great Britain at Panama, [illegible] the neutrality of the canal, and prepared to [illegible] that neutrality by erecting first-class [illegible] each approach. Not content with this, we proceeded to reaffirm the Monroe Doctrine by definite Congressional action, forbidding the acquisition by alien powers of harbors or coaling stations which were located within striking distance of the Panama Canal and which might serve as a base for hostile operations.

It is well understood that commercial rivalry is becoming more and more the predisposing cause of modern wars. Our opening of the Panama Canal will cause an upheaval in existing trade conditions and a quickening of commercial rivalries the like of which the world has never seen. Furthermore, its effect upon the balance of naval power, particularly in the Pacific, and in any conflict which may arise over the enforcement of the Monroe Doctrine, will be most profound. What Gibraltar and the Mediterranean were to the contending navies of the eighteenth century, the Panama Canal and the Caribbean will be in the future naval [illegible] of the New World.

And across this key to the commercial supremacy and the naval dominance of the Western Atlantic and the Pacific the United States stands, a colossus dominant and uncompromising.

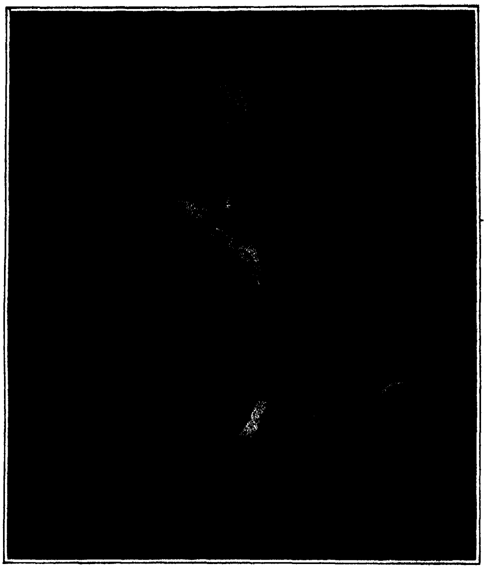
If we were slow in taking up our position as a world power, history will never charge that the United States was slow to assert the prerogatives of a world power. Not content with our reaffirmation of the Monroe Doctrine, which doctrine a recent friendly British critic has described as "the most magnificent bluff in all history; and, so far, the most successful," we have taken the vast problem of China into our benevolent keeping and have spoken out boldly for the "Open Door of Trade" as against Europe's pet theory of separate spheres of influence, thereby setting our face firmly against any attempt to destroy the integrity of that greatly coveted country. Lastly, we have looked squarely in the eye the most intelligent, refined, proud and successful of the Oriental races, and told it that we do not want and will not have its members in our midst. And this we have done to a people who, by defeating on land and sea the supposedly most powerful nation in the world, had but recently graduated, by universal consent, to the rank of a first-class naval and military power.

Such are the international policies of the United States in this year of our Lord 1914.

Discoursing on the subject of the policies of nations, a recent naval authority has this to say: "Modern science has made the nations of the earth neighbors, and modern thought has tempered the intercourse of many races, but national ambitions take life and grow as the nations prosper and, being like those of the individual, essentially selfish, the ambitions of one nation often excite the rivalry and opposition of another. So are born the policies of various peoples. When declared, these policies are but the formulated principles of conduct which the people of a State, or their Government, have adopted in the pursuit of their national well being. *When the policies of a State reach beyond its borders, they become of special interest to other States, for, as has been intimated, in these policies may be found the seeds of disagreement, perhaps of ultimate war.*"

Of such a character are our international policies. They are broad enough to bring us into most intimate contact with the policies of the other great powers of the world, and they are, therefore, big with possibilities of acute disagreement and ultimate war.

When a nation thus formulates its policies, it should



Copyright by Harris & Ewing.

Josephus Daniels, Secretary of the Navy.

Whether or not we shall have a first-class navy to enforce our policies depends in part on him.

[illegible] both the manner of their presentation to [illegible] nations whose interests may be affected and the subsequent attitude in case these policies should be [illegible]. It may offer them as a request, to be [illegible] or refused or ignored as the case may be, or it may boldly proclaim them as being so necessary to the national well-being and honor that they will be supported, if occasion should require, by all the armed forces of the State.

Now it is evident that to present such ambitious international policies as have been adopted by the United States in the form of a request would be as futile as it would be ridiculous—their very magnitude and daring [illegible] world at large as an intimation that we are prepared to defend them with all the available forces [illegible].

And this brings us face to face with the question: [illegible] power are we likely to possess in the near future, [illegible] power to resist such armed opposition, and by crushing opposition, enforce the consideration of our policies upon any future enemy or coalition of enemies? To this the answer must be made that, because of the geographical situation, a war for the maintenance of our policies must of necessity be a naval war, and that the navy of the United States is utterly inadequate to the magnitude of the task. The struggle for the enforcement of the Monroe Doctrine, the neutrality of the Panama Canal, Asiatic Exclusion, or the Integrity of China, will take place upon the high seas, and the situation is such that in the event of war to-day or to-morrow, we would find ourselves in the precarious position of having to defend first-class policies with a third-class navy.

We do not hesitate to say that the work of bringing the American navy up to the Standard of Strength called for by our national policies is by far the most pressing question now before the American people, its Congress, and its President.

It may be said of the people of the United States, as a whole, and to a great extent, of Congress itself, that they are so deeply engrossed with internal economic questions that they follow with a languid interest the course of international politics. It is only to a few in our Foreign Affairs Committees and in our diplomatic and naval and military services, that the portentous significance of the events which have led us to the present conditions have been known, and by them only has the alternative of either a disgraceful abandonment of our policies or a humiliating defeat in their attempted defense by inadequate naval and military forces been foreseen.

Universal arbitration, to which we all look forward with eager eyes, would present a way of escape from the existing dilemma, but the comparatively meager results of such Hague meetings as have been held, due to keen international distrust, has shown that this remedy is as yet in the far future.

And since arbitration is for the present at least but a beautiful dream, it behooves this nation to take careful count of things as they are and make at once a drastic readjustment between our policies and our sea power. We must modify our policies by retrenchment, or we must at once take all needful steps to bring the navy up to the full measure of its heavy responsibilities.

The nation is confronted with two alternatives, and two only. Either we must give up Guantanamo, Porto Rico, Hawaii, Guam and the Philippines; leave China to the rapacity of the Great Powers; dismantle our forts at Panama, placing the canal under joint international control, rename our first fighting line "coast-line battleships," and withdraw entirely within our own frontiers, or we must accept the burdens of a great world power, not with hesitation, but rather with a glad courage, remembering that these burdens are not of our own seeking, but have been laid upon us by a destiny against which there is no appeal!

The Scientific American and the Libraries

WE gather from a recent issue of the Boston *Transcript* that the SCIENTIFIC AMERICAN has been critically compared with every important periodical published in this country, with the result that it stands in a very special class of magazines favored by Massachusetts librarians. A committee was appointed at the fall meeting of the Massachusetts Library Club, which unanimously reported the following resolution:

> The members of the Massachusetts Library Club view with strong disapproval the alarming decadence in tone of many of the leading American periodicals, and emphatically protest against the tendency recently so manifest to cater to sordid sensationalism, indecent suggestion and to perverted taste.
>
> The committee has had several meetings, at which have been discussed the merits and demerits of certain leading periodicals, and it has prepared a list of fifty magazines which are recommended for small libraries, arranged in groups of ten, to cover the demands of libraries subscribing to ten, twenty, thirty, forty or fifty periodicals. This list it is proposed to print in the next issue of the Massachusetts Library Club Bulletin, and the committee also suggests that the State Library Commission publish it for distribution among the smaller libraries of the State. It is not to be understood that all of the reputable journals are included. The list is limited by the number chosen, and by the plan by which the committee endeavors to put in each group of ten magazines which should appeal to the various classes of a community. A list has also been made of twenty magazines, covering special subjects of a more or less technical nature. One or more of this special list could be inserted in the place of one in each group of ten, according to the demands of each locality.

In the first group, which comprises those periodicals which are indispensable to every library, however small, we find mentioned in company with the SCIENTIFIC AMERICAN, the following magazines: *Atlantic Monthly*, *Harper's Magazine*, *National Geographic Magazine*, *Outing*, *Outlook*, *Popular Mechanics*, *St. Nicholas*, the *Survey*, and the *Woman's Home Companion*. In group IV, which comprises magazines that are recommended to libraries which are able to pay for at least forty periodicals, the SCIENTIFIC AMERICAN SUPPLEMENT is recommended in addition to the *American City*, the *American Magazine*, *Bulletin of the Pan-American Union Republics*, the *Craftsman*, the *Dial*, the *Etude*, the *Illustrated London News*, *Popular Science Monthly* and *System*.

In Group III, which comprises magazines intended to cover the demands of libraries subscribing for thirty periodicals, we find mentioned in addition to *American Homes and Gardens*, which is published by Messrs. Munn & Co., Inc., publishers of the SCIENTIFIC AMERICAN, the *Boston Cooking School Magazine*, *Current Opinion*, the *International Studio*, *Modern Priscilla*, the *North American Review*, the *Review of Reviews*, *School Arts Magazine*, *Scribner's Magazine*, and the *Technical World*.

This analysis of current American periodicals is interesting and important because it shows how the Massachusetts Library Clubs Committee rates magazines in closely allied fields. *Popular Mechanics* and the SCIENTIFIC AMERICAN are evidently not regarded as covering the same field, for both are included in the indispensable magazines which even the library capable of subscribing for only ten periodicals should keep on hand.

All the publications of Munn & Co. find a place in one of the groups. The publications of the Century Company (the *Century Magazine* and the *St. Nicholas Magazine*), and Messrs. Harper Brothers, who publish *Harper's Magazine* and the *North American Review*, are the only other publishers of periodicals similarly honored.

Despite the flood of home and garden magazines which have made their appearance within the last ten years, only one other periodical of that type besides the *American Homes and Gardens* is mentioned in the groups, and that is the *Garden Magazine* of Messrs. Doubleday, Page & Co., which is included in Group II. *Country Life in America* is placed in a special list of twenty magazines "covering special subjects of a more or less technical nature."

Commenting upon the analysis the Boston *Transcript* states:

> "The report, and the accompanying lists, have allowed some librarians, inferentially and diplomatically, to ease their minds on the subject of some of the putrescent fiction which appears in a few magazines. This is a good thing.
>
> "It would be hard to estimate the exact amount of moral harm worked by this near-indecency in periodicals. Probably it is very small. The worst thing about it is the sickening insincerity of it all, and its result upon literary freedom After a few years in which a diluted form of sewage is offered under the name of 'red blood,' and slightly smutty stories are sold under the plea that art, truth, and frankness are in peril unless such stories are allowed, then there is apt to be a reaction in favor of prudishness. The news agent who whispers to you that he has got 'something shady' which he would like you to buy, may not be an admirable person, but he is worthy of rather more respect than the magazine editor who offers the same thing with a hypocritical plea that this is 'artistic truth.'"

Skating on Salt

By Walther Isendahl

NATURE has been conquered once more. Men can skate, not on ice, but on salt. A salt-skating rink, constructed by the patented process of Dr. Ed. Arnold, was recently exhibited and operated in Berlin

All skaters will welcome the invention of a method of producing, by purely chemical means and without the employment of a costly refrigerating process, a saline crystalline mass which exhibits all the characteristic properties of ice. The surface of the mass can scarcely be distinguished from a surface of natural or artificial ice, and the resemblance is increased by the fact that the shavings produced by the skates have all the appearance of snow. The mass is entirely odorless and contains no ingredient injurious to the health or the clothing of the skaters. It can be utilized for skating, with ordinary ice-skates, in every season and climate, except when the temperature is higher than 86 deg. Fahr.

The mass can be applied to any tight floor of wood, cement or asphalt, from which it can easily be removed by chipping or steaming. It is preferable to construct the skating floor in a building, but it may be installed in the open air, if it is protected from rain, drying winds, summer heat and direct sunshine by a shed, tent or other covering.

Boards can be coated with the mass and can be quickly assembled to form floors of any desired size, which can be taken apart as quickly. In this way temporary skating floors can readily be introduced on the stage and in public or private festivals, indoors or in the open air Slides for coasting can be constructed by a similar method.

The costs of construction and maintenance of a salt-skating rink are moderate The construction is very simple. The mass is melted and poured on the floor, where it quickly solidifies and forms a hard, smooth surface. It is applied in successive layers, each less than 1/25 inch thick. The cost of upkeep is small, for the "wear" is less than that of ice, especially at low temperatures, and the abraded "snow" is collected, melted with fresh material and used again The mass taken from old skating boards or rinks can be utilized in the same manner The quantity required for a single layer is less than 1/5 pound per square foot A fresh layer must be applied from time to time, with a freqency proportional to the use of the rink Two applications per week usually suffice. A surface of 5,000 square feet can be kept in condition by three hours' daily work of one attendant, in addition to occasional sweeping.

During an exhibition which was recently held in the exhibition building of the Berlin "Zoo" a demountable skating surface composed of wooden planks was used very largely and its durability was thoroughly demonstrated.

The Passing of the Sturgeon

IN his last annual report the United States Commissioner of Fisheries says that "the story of the sturgeons is one of the most distressing in the whole history of the American fisheries." For years these large, inoffensive fishes were supposed to be of no value, and when, as often happened, they became entangled in fishermen's nets, they were knocked in the head and thrown back into the water. When it was discovered that the sturgeon's eggs were valuable as caviar and its flesh as food a period of reckless fishing began, and in a few years the best and most productive waters were depleted, and what should have been made a permanent fishery of great profit was destroyed On the Atlantic coast the catch of sturgeon fell from 7,000,000 pounds to less than 1,000,000 in fifteen years, and an even more rapid decline occurred on the Pacific coast and the Great Lakes At present the total annual yield for the whole country is less than 1,000,000 pounds, and is decreasing. Meanwhile the demand for the eggs and flesh has steadily increased, with the natural result on prices. A mature female sturgeon now often brings more than $150. The worst of the situation is the fact that all attempts at artificial propagation have failed; so that, unless prompt steps are taken to protect the sturgeon by law, this fish will be practically extinct in American waters in a very few years. The Commissioner recommends that the legislatures of all States in which this fish exists or has existed should absolutely prohibit its capture or sale for a period of at least ten years. Meanwhile the Bureau of Fisheries proposes to transplant into our waters young sturgeon from foreign countries; especially a species from the Danube and the Caspian Sea, specimens of which have been offered by the Roumanian government.

Sikorsky's New Record

A DISPATCH appears in the New York *Times* of February 27th to the effect that on February 26th last the Russian engineer Sikorsky's biplane carried seventeen persons in a flight of 18 minutes' duration.

This is the second machine that Sikorsky has built Like its predecessor, it is huge, indeed by far the biggest flying machine ever constructed. No absolutely trustworthy dimensions have yet been published, nor have any really trustworthy details of the construction been given out. It seems certain, however, that the machine has a span of at least 80 feet, and that it is driven by four motors of 100 horse power each The passengers take up their places in an inclosed cabin of such size that seating and even sleeping accommodations are provided for some of them.

Wireless Weather Reports in the Indian Seas

WITH the rapid increase in the number and efficiency of the wireless telegraph stations on the coasts of India, it has now become practicable to issue daily weather bulletins by wireless to vessels over most of the Bay of Bengal and the northeastern part of the Arabian Sea. Six coast stations are open day and night, and any vessel-master can obtain the weather bulletin from the nearest of them on application The importance of the new service is due to the fact that both of the seas in question are notorious for their cyclones. These are most frequent in spring and autumn, but are likely to occur at almost any time.

At Work on the Lincoln Highway

THE accompanying photograph is a 5-ton motor truck at work on the Pennsylvania State Highway. Construction is under way from Philadelphia to Pittsburgh, and when completed this road will be part of the coast to coast Lincoln Highway. Four and five trips constitute a day's work, a round trip averaging ten and one half miles. Loading time is about twenty minutes, as it is done by a gang of four men with hand shovels. The grades on this particular stretch of road are all the way from eight per cent to twenty-five per cent.

Novel Method of Ice Sawing

IMPROVED methods of sawing ice are receiving increased attention to-day on account of the high cost of labor and large number of men needed to harvest a cut. A recent development in this field is shown in the accompanying photograph, which illustrates the application of the electric drive to multiple sawing in a channel located just outside the ice house. Instead of cutting the ice into small blocks on the lake surface and then poling it to the house at the risk of re-freezing, the ice is now cut on the pond into cakes 12 feet long and 18 feet wide, after which the cakes are put through the saws longitudinally and transversely, and are thus cut into 63 blocks per cake and fed into the house at the rate of about 5,000 tons per day of 10 hours. The saws are 36 inches in diameter and are run by electric motors mounted on a temporary platform at one side of the channel. A saving of about $100 a day is effected as compared with the old method of sawing on all parts of the lake, the reduction in labor and teams required being a striking feature.

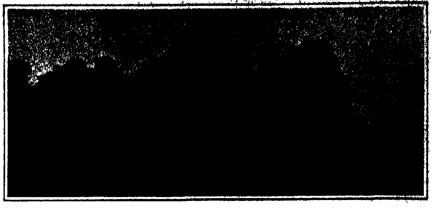
Electrically-controlled Shutter for Automobile Headlights

TO meet the conflicting demands of motor car drivers and city authorities, the headlight shown herewith has been designed. It consists of two pairs of translucent wings mounted on pivots or bearings fastened in the headlight reflector. These wings are made to open and close by electro magnets situated inside the cover of the lamp itself. When running in the city, where it is necessary to use reduced light in the headlights and avoid glare, the wings are closed simply by pressing a push button conveniently situated on the dash. When the wings are closed, there is absolutely no glare, but the road near the car is flooded with strong, diffused light, a fact which makes the lamp particularly valuable when rounding sharp curves. At any moment when it is desired to use the full illumination of the lamp, it is only necessary to push another button which opens the wings, and the concentrated search light beam is at once available.

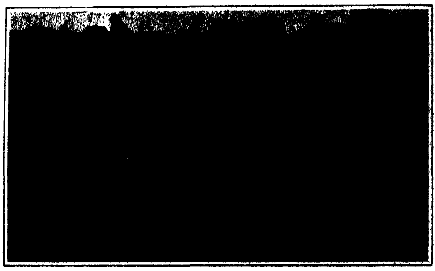
When in the folded or open position, the wings do not perceptibly affect the light given off by the lamps, as they are very thin and are so placed that they do not perceptibly obstruct the rays of the headlights when folded. The electro magnetic control is extremely convenient, and it takes only a small current from the battery just at the moment when the wings are either opening or closing. The power required for operating the electro magnet is less than half that required by the average electric horn.

Modern Pipe Casting

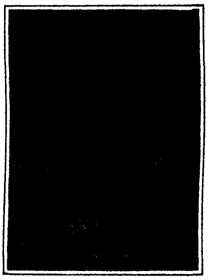
AN interesting development in pipe-foundry labor-saving methods that has come into almost universal use at the present time is the subject of the accompanying illustration. This is a multiple-lip ladle so constructed that it pours from four points at once. Six foot gas and water pipe, and standard five foot soil or waste pipe has always been cast horizontally as in the picture, the multiple pouring having been used, as this gave a more perfect pipe. The shifting of cores and the consequent varying of wall thickness in the pipe was largely eliminated and a more perfect distribution of the liquid metal obtained. [illegible] sary, however, for the [illegible] pouring to make a great [illegible] nearest source of supply [illegible] whether that was the furnace [illegible] bull ladle, filled at the furnace [illegible] to the most advantageous [illegible] pouring also took a long tim[illegible] men could not be put on to [illegible] process as they would merely [illegible] others' way. Each man could [illegible] comparatively smal amount [illegible] the work that could be done [illegible] limited in each instance by [illegible] capacity of the workman inv[illegible]



At work on the Lincoln highway.

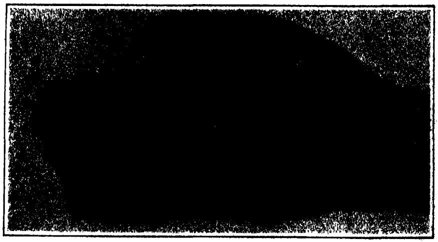


Sawing large cakes of ice into smaller cakes for storage in the ice house.

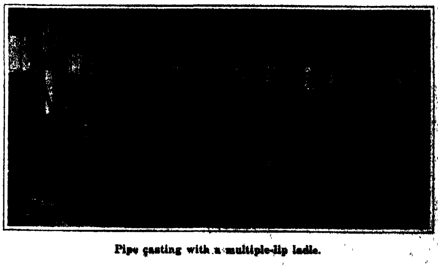


Headlight with reflector cut off.

Headlight with the shutter open.



Pocket wireless receiver for time signals.



Pipe casting with a multiple-lip ladle.

It was to get away from [illegible] limiting factors that induc[illegible] operators to devise and de[illegible] tiple-lip ladle for pipe pour[illegible] ladle is built in the shape of [illegible] iron bath tub, lined of cour[illegible] to prevent its rapid burn[illegible] supported at each end by [illegible] in a bearing formed by the [illegible] an arm that hangs from a cha[illegible] hoist in turn is supported on [illegible] craneway that is part of an ov[illegible] system, centering at the cupol[illegible] and extending over the floor [illegible] which the casting is done.

These ladles are filled directly [illegible] cupola and will hold half a ton o[illegible] iron. The workmen are protected [illegible] great radiated heat of the molten [illegible] shields either fastened to the su[illegible] arms, or, as in the picture, cove[illegible] ladle itself. Long handles attached [illegible] side of the ladle at its opposite ends [illegible] means for tilting and guiding the l[illegible] that it will deliver the iron through th[illegible] lips into the proper openings provid[illegible] the top of the pipe mold.

Vest Pocket Wireless Rece[illegible]

THE value of the new French [illegible] phone" detector, for receiving w[illegible] signals, lies in its very small size and [illegible] pact make-up, so that the whole affair [illegible] be carried in the vest pocket. It is desi[illegible] to meet the growing demand among [illegible] public for a device which will enable a[illegible] one to hear wireless time signals from [illegible] Eiffel Tower station. When it is once [illegible] preciated that the time signals can be tak[illegible] without the use of a complicated device and with little knowledge of electricity, there is no doubt that a much more general use will be made of the wireless time signal system. To show what can be done with the little detector, we may mention that at 20 miles from Paris, all that is needed is an open umbrella held as high as the arm can reach, while a small metal contact piece attached to a cord lies upon the ground and makes the earth connection. At 60 miles one plants a knife in a tree, preferably a pine tree, or a gimlet will answer as well. One of the cords with its metal clip is joined to this "antenna," while the other clip is placed on the ground. The entire receiver weighs but 13 ounces, and yet, in spite of its small size, it is carefully made and is an apparatus of great precision. For long distances, to the extreme borders of France for instance, and even farther, one clip is joined to a telephone line which serves as an antenna, and the other goes to gas or water pipes for the ground. But within 120 miles, all that is needed for the antenna is a kitchen stove or range, balcony, metal bed and the like, and even a bicycle on the road makes a good antenna, or an automobile. The operator may use his body for the ground by attaching the metal clip to his finger, while the other clip goes to the telephone wire. In this way signals were received from Paris at a distance of 270 miles.

A Danish Typewriter Contest.—In a typewriting contest held at Copenhagen, at which machines from leading manufacturers were entered, there were sixty-nine competitors, and about forty of the operators contesting for prizes used American machines. It is interesting to note that the first, second and third prizes were all won on American typewriters, and only two contestants using machines other than American succeeded in receiving [illegible]

How the Locks of the Panama Canal are Operated

The Wonderful Control Boards Which Enable a Single Man to Operate Gates Weighing Tons and to Govern the Course of Thousands of Gallons of Water

The electrical mechanism, which will operate the ponderous locks at Gatun, Miraflores and Pedro Miguel in the Panama Canal, is quite unlike anything used elsewhere in the world. Heretofore it has been the practice to locate a large operating force practically along the length of the locks in a canal. Such a force is difficult to co-ordinate into an efficient operating system. However, the enormity of the Panama locks made it most desirable that all operations should be centralized. The flight of locks at Gatun, for example, extends over a distance of 6,152 feet, and the principal operating machines are distributed over a distance of 4,115 feet.

The Isthmian Canal Commission decided that the locks must be electrically controlled from some central station in each case, because thus the number of operators, the operating expense, and the liability to accidents could be reduced. Great electrical control boards have therefore been especially invented which are installed at Gatun, Miraflores and Pedro Miguel—control boards which are so ingeniously conceived and constructed that a single man, who need never see the ships which are passing through the canal, opens and closes lock gates weighing many tons and governs the course of thousands and thousands of gallons of water.

How the Locks Are Arranged.

Before we can understand how this is done, we must explain how the locks themselves are constructed and what is the character of the lock machinery to be controlled.

As readers of the SCIENTIFIC AMERICAN know, the lock chambers are 1,000 feet long. At each end of a lock chamber, so-called "mitering gates" are to be found, which consist of two massive leaves pivoted on the lock walls and which operate independently of each other. Immediately beyond each pair of mitering gates at each end of a lock chamber a duplicate pair of mitering gates is to be found. These are guard gates. Lastly, still other mitering gates open and close within the lock chamber itself. These, which are called "intermediate mitering gates," are used to divide the 1,000-feet locks into smaller compartments when vessels of short length are to be handled. Thus much water is saved. All the mitering gates, when closed, are clamped tightly together by a device called a "miter forcing machine."

In front of all the mitering gates which are exposed to the upper lock level and also in front of the guard gates at the lower end are chain fenders. These chains are taut when the gates behind are closed and are lowered when the gates are opened for the passing of a ship. The chains are raised and lowered by a method similar to that followed in hydraulic elevators, with the additional feature that if a ship approaches the gate at a dangerous speed and runs into the chains, the chain is paid out in such a way as to stop the ship gradually before it reaches the gates. Two motors lower the chains for the passage of a vessel and raise it again after the vessel has passed. One motor drives the main pump supply water under pressure, and the other operates a valve which controls the direction of movement of the chain. These two operations are combined in one, each motor being stopped automatically by a limit switch when the motor has performed its function.

How the Water Flows from Lock to Lock.

The locks are filled and emptied by three culverts, one in the middle wall and one in each side wall. The flow of water is controlled by what are known as "rising stem valves." These valves are located in the culverts at points opposite each end of each lock, so that the culvert can be shut off at any desired point for filling a lock with water from above, or upstream, or for emptying it by allowing it to flow out and down to the next lock. Lateral culverts conduct the water from the main culverts under the lock chambers and up through openings in the lock floors.

The rising stem valves are installed in pairs, and each pair is a duplicate. Moreover, each culvert is divided into two parallel halves at these valves by a vertical wall. This arrangement reduces the size of each valve, so that it may be more easily operated. Even then, each valve measures 8 by 18 feet and is raised and lowered by a 40 horse-power motor requiring one minute for complete closing. One pair of duplicates is kept open as a guard or reverse pair; the other pair is used for operating, so that in case of an obstruction in the culvert or of an accident to the machinery, the duplicate pair can be used.

At the upper ends of the culverts at the side walls, the duplication is accomplished by three valves in parallel, called the guard valves. Their service is exactly similar to that of the rising stem valves, except that three valves in parallel in this case must conform with the same laws as the two in parallel in the other case.

The culvert in the middle wall must serve the locks on both sides, and to control this feature, cylindrical valves are placed in the lateral culverts that branch out on each side. There are ten of these on each side of the culvert at each lock.

At the upper end of each set of locks, there are two valves in the side walls for regulating the height of water between the upper gates and upper guard gates, as it is desired to maintain the level of the water between these gates at an elevation intermediate between that of the lake above and that of the upper lock when the upper lock is not at the same level as the lakes. These valves are called the auxiliary culvert valves.

Five Hundred Motors Operate the Lock Mechanism.

To give an idea of the number and sizes of the motors to be controlled in operating the lock machinery it may be mentioned that each miter gate leaf is moved by a 25 horse-power motor. There are forty such motors at Gatun, twenty-four at Pedro Miguel, twenty-eight at Miraflores, a total of ninety-two, with an aggregate horse-power of 2,300. Each miter-gate forcing machine is worked by a 7 horse-power motor. Of these motors there are twenty at Gatun, twelve at Pedro Miguel, fourteen at Miraflores, a total of forty-six, with an aggregate horse-power of 322. So, at Gatun, Pedro Miguel and Miraflores there are in all forty-eight motors of 70 horse-power each, which work the main pumps of the fender chains and which have an aggregate horse-power of 3,360; forty-eight motors of ½ horse-power each for operating the valves of the various fender chains and which have an aggregate horse-power of 24; one hundred and sixteen motors of 40 horse-power each which operate the rising stem gate valves; one hundred and twenty motors of 7 horse-power each which operate the cylindrical valves; eighteen motors of 25 horse-power each, which operate the guard valves; and twelve motors of 7 horse-power each which operate the auxiliary culvert valves. Hence, there are five hundred motors of various kinds at Gatun, Pedro Miguel and Miraflores, with an aggregate horse-power of 12,020, to be controlled.

The Wonderful Electrical Control Boards.

The electrical control boards which control all these many motors, valves, and pumps were designed and built at Schenectady, New York, from specifications prepared under the supervision of Mr. Edward Schildhauer, electrical and mechanical engineer of the Isthmian Canal Commission, ably assisted by Engineers C. B. Larzelere, W. R. McCann, and others, and will long be used as models of skilled and painstaking engineering in which every contingency was foreseen and all the safeguards installed that expert engineers could suggest.

The control boards for each lock are to be found in control houses located on the middle walls at points which afford the best view of the locks, although this view is not depended upon to know the position of the gates or other apparatus.

The control boards are approximately operating miniatures of the locks themselves. They have indicating devices which always show the exact position of valves, lock gates, chains and water levels in the various lock chambers, and so far as was necessary are synchronous with the movement of the lock machinery.

The control boards are flat benches 32 inches high by 54 inches wide, built in sections. The board at Gatun is 64 feet long; that at Pedro Miguel 36 feet long and that at Miraflores 52 feet long.

The side and center walls of the locks are represented on the board by cast iron plates and the water in the locks by blue Vermont marble slabs.

The Indicators and How They Work.

In designing the indicators efforts were made to represent the actual machines, the operations of which were to be indicated. For example, the chain fender index consists of a small aluminium chain representing the larger chain of the lock itself. Just as the large chain is lowered into a slot in the bottom of the lock, so the small chain is lowered into a slot in the top of the board. With equal fidelity the miter gate is reproduced. The miter gate indicator consists of a pair of aluminium leaves or pointers which represent a pair of the large miter gates and which move in a horizontal plane just above the marble slab representing the water in the lock. The rising stem valve indicators, however, presented a more serious problem, because the valves themselves are located in a culvert and the operating machinery is concealed below the lock wall; yet for the purpose of observation it was necessary that the indicators project visibly above the surface of the board. The rising stem gate valves of the locks, it has been stated, occur in pairs. For that reason the indicators for these valves have likewise been made in pairs on the board. Each of these indicators may well be likened to a miniature elevator, the car being used to indicate the position of the valve gates. In order that the indication might be visible from various points up and down the board, a novel scheme was resorted to. The underside of the car is equipped with reflectors so arranged as to reflect, parallel to the surface of the board, the light of several incandescent lamps located underneath the board. This light is reflected through openings in the indicator facing both up and down the board, the openings being closed with opal glass. The reflected light gives a sharp shadow on the bottom edge of the car, all portions of the indicator above this line being dark and all portions below being illuminated. The illuminated portions show how far the gate of the valve is open. If the indicator is dark, the valve is entirely closed; if the indicator is illuminated, the valve is entirely open. The one quarter, one half, and three quarter positions of the gate are indicated by heavy black lines on the glass.

For the water level indicator, great accuracy was required. The specifications demanded that the level of the water be indicated to within five eighths of an inch of the actual level, but the indicators attained an accuracy somewhat greater than this. The height of the water is indicated by a rising and falling hollow cylinder having pointers which move over scales. The scales are illuminated by tungsten lamps, located in both the base and the top cap of the indicator.

The indicators for the miter forcing machines, which force the end surfaces of the lock gates into alignment, are not operated by means of position indicator machines. Since all the operator cares to know about them is whether they are in the open or closed position, they are operated merely by control switches.

The open and closed positions of all cylindrical valves are indicated by means of red and green lamps, the intermediate positions not being indicated in any way because the operators need not take cognizance of them.

The Interlocking System, Which Prevents Mistakes.

In order to make it necessary for the operator to maneuver the control switch handles always in a certain order, corresponding with a predetermined sequence of operation of the lock machinery, and to prevent the operator in control of one channel from interfering with the machinery under jurisdiction of the operator controlling the other channel, an elaborate interlocking system has been devised.

The limitations of space forbid an elaborate description of this wonderful interlocking mechanism. The interlocking system is essentially a bell crank mechanism, connecting the shaft of the control switch directly to a movable horizontal bar, forming one of many such bars in an interlocking rack below the control board.

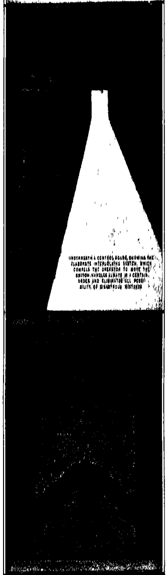
From one of the accompanying detailed illustrations it will be seen that a horizontal connecting rod is used between the cranks on the control switch shaft and the vertical operating shaft. The interlocking rack consists of a rigid frame constructed of three eighths inch thick steel and having five horizontal members. Upon these horizontal members and tying them together are located at convenient intervals a set of vertical straps of three eighths inch by two inch steel. These carry the brass posts that provide the runways for the horizontal and vertical interlocking bars.

The back of the steel strap is grooved and countersunk in such a manner that a key is provided which prevents turning of the posts.

The interlocking system depends mainly on the action of engaging bevel dogs located on the horizontal and vertical bars, the movement of a horizontal bar tending to lift a vertical bar by bevels on the dogs. A horizontal bar cannot be moved without raising a vertical bar. Thus, if at any time a dog on a horizontal bar rests against the upper end of a dog on a vertical bar no movement of the horizontal bar where the dog engages the vertical bar can take place, and the control handle connected with that particular horizontal bar is locked.

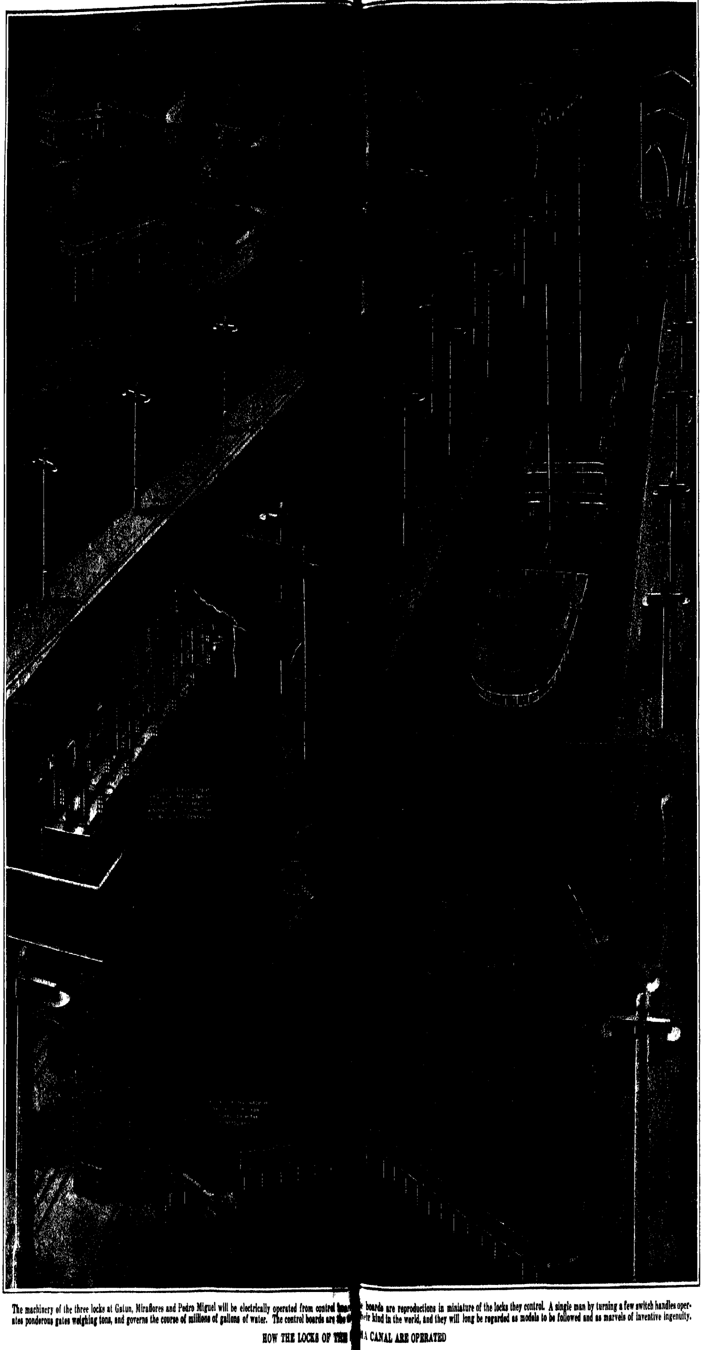
The interlocking system forces the attendant to operate the chain fenders, gates and valves always in the proper sequence, and also prevents him from operating

(Concluded on page 214.)



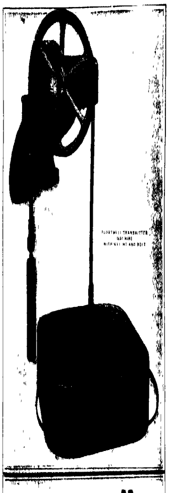
UNDERNEATH A CONTROL BOARD, SHOWING THE ELABORATE INTERLOCKING SYSTEM, WHICH COMPELS THE OPERATOR TO MOVE THE SWITCH HANDLES ALWAYS IN A CERTAIN ORDER AND ELIMINATES ALL POSSIBILITY OF DISASTROUS MISTAKES

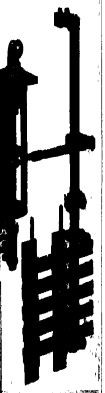
The indicating devices on the control boards show the positions of the rising stem and other valves, lock gates and the water level as it changes in the various locks and in the forebay.



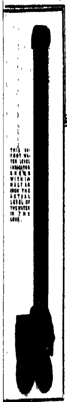
The machinery of the three locks at Gatun, Miraflores and Pedro Miguel will be electrically operated from control boar e boards are reproductions in miniature of the locks they control. A single man by turning a few switch handles operates ponderous gates weighing tons, and governs the course of millions of gallons of water. The control boards are the heir kind in the world, and they will long be regarded as models to be followed and as marvels of inventive ingenuity.

HOW THE LOCKS OF THE A CANAL ARE OPERATED

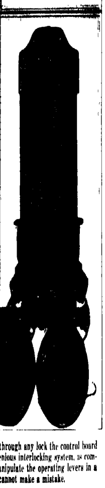




THE INTERLOCK SYSTEM IS ESSENTIALLY A BELL CRANK MECHANISM, CONNECTING THE SHAFT OF THE CENTRAL SWITCH THROUGH A MOVABLE HORIZONTAL BAR WITH A VERTICAL OPERATING SHAFT WHICH CAN OR CAN NOT MOVE ACCORDING TO THE RELATIVE POSITIONS OF THE INTERLOCKING BARS AND DOGS



THIS 50-FOOT WATER LEVEL INDICATOR SHOWS WITHIN HALF AN INCH THE ACTUAL LEVEL OF THE WATER IN THE LOCK.



THE RISING STEM VALVE INDICATOR

In passing a vessel through any lock the control board operator, by an ingenious interlocking system, is compelled always to manipulate the operating levers in a definite order. He cannot make a mistake.

A Motor Lifeboat With a Cabin

No matter how safe a vessel may be rendered by means of bulkheads and double bottoms extending well above the waterline, the danger of fire, of a boiler explosion or of pounding to pieces on rocks or shoals makes it essential that every vessel be fitted with lifeboats. Recent disasters at sea show how difficult it is to launch a lifeboat of the ordinary type from a vessel in time of storm and also how readily the ordinary open lifeboat may be swamped. At the recent Motorboat Show held in New York a motor lifeboat was exhibited which was identical in design with the self-righting, self-bailing motor lifeboat used in the United States Life Saving Service, with the additional feature of a completely inclosed cabin. The boat is 36 feet long and provided with a 35 to 40 horse-power internal combustion engine capable of driving it at a speed of 10 to 11 miles per hour, fully loaded. The engine which may be operated on gasoline, kerosene or distillate fuel is placed in a water-tight compartment in the stern with all the controls on the outside, so that there would be no chance for the engine to be overwhelmed by a wave. Furthermore, the smoke and engine smells are kept out of the cabin. The gasoline tanks are on the outside and above the waterline where any leak would drain overboard. Into the cabin 60 or 70 passengers may be crowded and kept where their frantic and hysterical actions will not bother the pilot of the boat. In addition to the engine the boat is provided with a wireless telegraph system whereby communication could be established with rescue ships.

As the principal danger lies in the launching of a lifeboat, the builders of this lifeboat had designed a simple launching system, the rudimentary principles of which are shown in the accompanying illustration. On the boat deck a system of tracks is laid and the lifeboats are supported on roller trucks which run along the tracks and are thus brought to the launching point on the leeward side. Here they are picked up by a simple crane consisting of a pair of arms fulcrumed at the side of the vessel and connected at their outer ends by a cross-arm. By means of an automatic clutch the boat is instantly secured to the cross-arm and then the crane is swung out over the side of the vessel, coming to rest with the keel of the lifeboat about 15 feet lower than the boat deck. Here the lifeboat is supported far enough out to prevent it from being smashed against the side of the vessel. The pilot then awaits his opportunity. As soon as a wave dashes up to within 10 feet of the keel of the lifeboat he operates a release lever which drops the boat into the water. The lifeboat is so stanchly constructed that it may take a drop of 10 feet or even more without injury. As soon as it strikes the water it is carried off from the boat by the receding wave, and the engine which previously has been started, immediately carries it clear of the wreck. In case conditions do not permit of dropping the boat directly into the water, an inclined monorail system has been designed which may be attached to the side of the boat in such manner that it may fold against the hull or may be extended, when desired, so that it will form an extension of the cross-arm of the crane. Down this inclined monorail the boat glides under control of the operator until it reaches a point where it may be dropped into the water. It is impossible for us to judge of the practicability of these proposed launching methods as we have not been acquainted with the essential details. The boat, however, whether launched in this manner or by well-known methods now in use, should prove almost invaluable in case of a serious accident at sea.

A self-righting, self-bailing, motor lifeboat with cabin accommodating sixty passengers.

The Molecular Air Pump

A great deal of interest has recently been aroused in the introduction, by Dr. Gaede, of an interesting type of air pump. It has particular value in connection with the exhaust of gases from bulbs, tubes, and similar apparatus requiring a high internal vacuum.

The principle of the apparatus is shown in Fig. 1. A is a cylinder fixed on a shaft a and inclosed in a casing B, into which is cut a groove reaching from n to m. When the cylinder A rotates as shown by the arrow, the air contained in the groove is entrained from n to m by the friction. On connecting a gage o to the apertures m and n by pieces of rubber tubing S, it shows a difference of pressure between m and n. The level of the mercury rises to the point p and is depressed to o at the other end. The difference of pressure is proportional to the number of revolutions of the cylinder A and the internal friction of the gas.

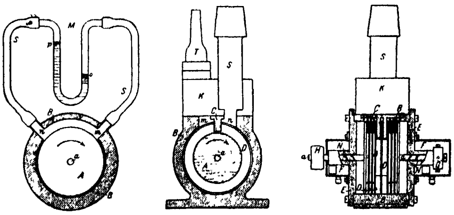

Fig. 1 Fig 2 Fig. 3

Diagram and sectional views of the new vacuum pump.

This internal friction, according to the kinetic theory of gas, is produced by the collisions continually occurring between the moving molecules of the gas. The molecules move with a very high velocity in rectilinear paths, the direction of which is absolutely irregular until they meet with other molecules. At ordinary pressure the result of this is an irregular, zigzag motion. At very low pressures, however, the collisions of molecules among each other become very rare owing to the high degree of rarefaction, so that the molecules of the gas may be said to impinge exclusively on the walls of the vessel containing them. From the walls the molecules are reflected quite irregularly, the angle of reflection being independent of the angle of incidence. If the surface of the cylinder A moves with a higher velocity than the molecular velocity of the gases, the effect of vessel moving to the right with a higher velocity than that of the molecules projected out of it to the left is that the molecules projected toward the point n are nevertheless entrained to the right in the direction of the arrow in the figure. No molecules reflected from the cylinder will therefore reach the aperture, which will be a region of fewer molecules—in other words, a vacuum will be formed at n.

Evidently this pumping arrangement is not so useful at atmospheric pressure as at low pressure in connection with a backing or rough pump, as the action of the pump is based on the molecular action of the gases. Figs. 2 and 3 show the actual construction of the cylinder A fixed on the shaft, a in the case B. The shaft runs in bearings provided in the end-plates E of the cylindrical casing which are screwed on air-tight. The grooves D are cut into the cylinder, and the tongues C which are fixed on the casing project into the grooves. F are the oil tanks, G is an adjusting gear by which the tongues C are kept from touching the rotating walls of the grooves. H is the pulley. When A rotates clockwise, the air is compressed at m and rarefied at n. The extension K is fixed by screws on the casing B, forming an air-tight joint. S is the suction nozzle which communicates with the space n in the casing, the groove D shown in the cut being the central groove of the pump. The discharge air pressure opening m of this groove is connected with the suction opening of the adjoining groove by a channel bored in the extension K, the pressure opening of the

(Continued on page 216.)

Fig. 4.—General view of the molecular pump.

Fig. 5.—Pump belted to a motor which drives it at 8,000 to 12,000 revolutions per minute.

RECENTLY PATENTED INVENTIONS

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN.

Pertaining to Apparel.

ADJUSTABLE BANDEAU FOR LADIES' HATS.—B. WERTHEIMER, care of F. F. Eiseman, 41 Park Row, New York, N. Y. This invention provides an adjustable bandeau for ladies' hats, arranged to enable the milliner or other person to readily increase the size of the bearing portion of the bandeau to suit the head of the customer, thus insuring a proper fit of the hat.

CORSET COVER.—L. T. FURNAS, Lima, Ohio. This invention refers to a garment in the form of a corset cover or brassière which is adapted for contraction or expansion at both top and bottom and intermediately on a vertical median line for giving a desired contour to the bust and waist.

Pertaining to Aviation.

AEROPLANE.—A. E. HOLBROOK, Joplin, Mo. The purpose here is to provide a machine wherein a maximum of lifting surface is obtained with the smallest possible amount of weight, wherein the balancing will be automatic, and wherein a plurality of rudders is provided operated by a single shaft.

FLYING MACHINE.—R M METCALF, Route 3, Valley City, N. D. This invention relates to a flying machine of that type known as self propelled aeroplanes; and the aim is to provide a device which will be simple, of light weight and great strength, which will run at a high speed and in a steady manner, and which will be capable of easy control.

Of Interest to Farmers.

CULTIVATOR.—R. DINSE, Stanwood, Iowa. The object here is to provide a device by means of which plants in rows may be cultivated on all sides, while the cultivator is moving longitudinally of the rows, thus dispensing with the necessity for hoeing or cultivating at right angles to the direction of the rows

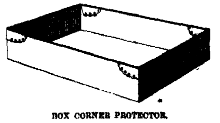
LINE GUIDE -A. C. OHNSMAN, care of J. L. Ohnsman, Sta. A, Route No. 5, Columbus, Ohio. The object here is the provision of easily transportable means for holding a line at each end of the field to be planted, so arranged that the line will be held tight during the planting, and when the row is planted the succeeding line will be indicated.

ELECTRICAL AGRICULTURAL SYSTEM.—C. S. DONEY, Wallace, Idaho This invention provides a means for supplying power to agricultural tractors or motor vehicles such as gang plows, cultivators, seeders and the like, which will permit them readily to move over the ground. It provides means whereby a trolley on the motor vehicle will move the wires from which it receives current to and fro as the tractor traverses the field.

WIRE WINDER—C. B. RUBY, Le Mars, Iowa. The inventor provides a device wherein means is provided for holding and rotating a reel, together with means capable of being operated from a point adjacent to the reel, for constraining the wire to wind in uniform layers upon the reel. When taking down a fence, the frame may be moved as a sled or with wheels, winding up the wire as the device moves along the fence.

Of General Interest.

BOX CORNER PROTECTOR—KATHERINE M. BLACK, 407 E. 11th St, Austin, Tex. This protector is constructed of a piece of metal with an angular cutaway portion at its inner side so that the piece of metal may be bent longitudinally and transversely through the apex of the angle formed by the cutaway portion to fit a corner of the box or box lid without the inner side of the piece of metal overlapping. The edge of the piece of metal is scalloped, and the edges of the scallops are turned inward to engage the surfaces of the sides of the box to obtain a grip thereon and prevent protruding edges of metal from catching goods in the box. The outer sides of the metal have punched portions forming spurs which project inward and which engage similar spurs on the inner sides of the metal, which project outward.

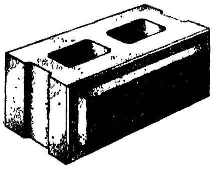


BOX CORNER PROTECTOR.

MOLD FOR EARTHENWARE.—A. FOLTZ, Lambertsville, N. J Address L. P. Kugler, same place. An object of the inventor is to provide a device by means of which an article, such as a tank, may be molded by passing a stream of water containing particles of clay or other suitable materials in suspension, into the mold, where the clay is deposited, the water being forced out by pressure.

TABLET.—W. K. WATERMAN, 12 South 18th St., Flushing, New York, N. Y. This tablet is for use on the outside of office buildings, stores, banks, etc., and arranged to be legible during the day and night by evenly illuminating the panel or background to render the opaque letters distinctly visible, project but little from the face of the structure to which the tablet is attached, and to give the tablet an exceedingly artistic appearance.

BUILDING BLOCK AND METHOD OF FORMING THE SAME.—F. AARONSON, Manasquan, N. J This invention provides blocks with undressed faces; provides said blocks with roughened faces, such faces being formed without design; provides a molded block having an unmolded face and provides a block having a face roughened by forcibly separating said face from a body of the same material, The grain of the material, instead of being, as at present, closed or filled, has much of the porosity of fracture lines of a natural rock.



BUILDING BLOCK.

MOUSE PROOF PIANO PEDAL—R BOLLERMAN, care of Bollerman & Son, 271 E 132nd St., Bronx, N Y This invention has particular reference to means for effectively excluding mice from the interior of the piano The invention provides a means for use in connection with a piano pedal which will automatically close the opening ordinarily left by the pedal when in its normal elevated position

TRUSS.—J T HAILE, Utopia, Tex The invention provides certain improvements with respect both to the truss pad and the adjustable connections for securing the same to the wearer, whereby to form a more sanitary, more comfortable and more beneficial device than is now in use.

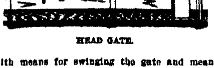
ELEVATED CARRIER—A. D HADSEL, care of Cable Excavator Co., 410 Arcade Bldg, Philadelphia, Pa. This carrier includes a cableway which may be of considerable length and along which is adapted to be operated a main carriage for the purpose of supporting any suitable form of excavator bucket or means for handling material in general, including the loading and unloading of barges or other craft or transfer of vessels to cars or handling of stone in quarries or the like.

COMBINATION WRITING PAPER AND ENVELOP TABLET—J ANDERSON, U S. S "Utah," care of Postmaster, New York, N Y The invention relates particularly to a tablet in which sheets of writing paper and a series of envelop blanks are so combined that the paper and the blanks have a compact and convenient arrangement, with the blanks spread out in flat form and superposed one on another, the paper and the blanks being held to stubs defined by lines of perforations or their equivalent, so that the letter sheets and blanks can be readily detached as required for use

PROCESS OF MOUNTING EYE SPECIMENS.—F L. BARROWS, Moscow, Idaho The process consists in placing fresh eyes (preferably pig or sheep) for mounting in a formalin solution to harden the same, then freezing and dividing them into two parts, keeping such parts immersed in an aqueous solution until the vitreous portion has dissolved out and gelatin has taken its place; then removing the eye portions and immersing them in soft gelatin to solidify

HOLDER FOR PACKING BOXES.—NETTIE C LYND, Oregon City, Ore. An object of this invention is to provide a holder for packing-boxes such as boxes or crates used in packing oranges, grape fruit, or other fruit which will obviate the necessity of lifting the box and turning it around during the packing operation

HEAD GATE.—J T FITCH, Helper, Utah. The object of the invention is to provide a simple, strong, inexpensive and balanced gate which can be quickly and easily operated and which is provided with means for indicating the size of opening formed by the gate This invention provides a gate adapted to swing in a plane normal to the flow through the gate, with means for swinging the gate and means indicating the size of opening made by the gate The gate being centrally pivoted in a vertical axis, the pressure of water in the gate at any position of the gate is necessarily balanced; thus no extra power is required to operate the gate.

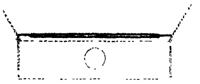


HEAD GATE.

NON-REFILLABLE CIGAR BOX.—J. GAGLIANO, 122 Jamaica Ave., Astoria, N. Y., N Y. This invention provides means for handling or dispensing the better grades of cigars, cigarettes or the like. It provides a means whereby cigars may be handled in bulk in such form that the individual cigars cannot be touched or handled, and hence are kept in a perfectly clean and sanitary condition

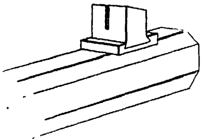
HORSE OVERSHOE—J J. O'CONNELL, R F. D. No. 1, Box 119, Ridgewood, N. J The invention pertains to farriery and has particular reference to a temporary attachment or overshoe to be applied in slippery or icy weather to prevent the ordinary horseshoe from slipping when the calks thereof, because of being blunt or otherwise, will not hold the horse securely

STRAINER ATTACHMENT—G BENDIX, Vesta, Minn The purpose here is to provide a device whereby a strainer for milk or other fluids may be quickly repaired without the necessity of dismantling the device The article may be used with an ordinary milk strainer and its use will practically render the strainer as good as new. An annular ring with the screen or wire cloth is made up in various sizes to accommodate strainers of greater or less capacity. The rings are made full width so that they may be trimmed if necessary Ordinarily, however, this would not be required



STRAINER ATTACHMENT.

FRONT GUN SIGHT.—A. J EVANS, Box 157, Mosier, Ore. The purpose of this sight is to secure greater accuracy in elevation and line in target and game shooting It is of the type of leaf or block sights having a notch or vertical slot in the center In practice, when the sight is used on military and sporting guns, the surface next to the eye should be finely matted or black The sight permits an unobstructed vision of the bull's eye or target, and in raising the gun the horizontal line of the top of the sight quickly indicates the required elevation, while the vertical slot quickly directs the vision in line with the objects



FRONT GUN SIGHT

CAPSULE—M H SMITH 105 Chamber St, New York, N Y This capsule is provided at its inner face with a raised identification mark of the same material as the capsule and integral therewith, the capsule being filled with a liquid medicine having approximately the same index of refraction as the capsule so that the identification mark is not discernible from the outside

PROCESS OF PRODUCING A PHOTOGRAPHIC REPRODUCTION FOR USE IN MAKING BAS-RELIEF—G M CARPENTIER, 175 W 95th St, New York, N. Y This invention relates to a process for producing photographic reproductions in relief of designs paintings engravings, or photographs of any description with absolute fidelity of form and in any given size of the objects or figures the artist intended to represent.

Hardware and Tools.

PNEUMATIC TOOL—E M TOBIN, Barre, Vt. The invention relates to improvements in pneumatic tools, and particularly to what are known as pneumatic hammers, and has for an object to provide a structure wherein the various moving parts are reduced to a minimum, and the action is without unnecessary vibration or jars

DENTAL MASSAGE IMPLEMENT—M POUNDER and F. F HANSKE, Munger Bldg, Elkhart, Ind. The object here is to provide an inexpensive implement which may be used to massage the gums of the oral cavity to provide and stimulate healthy circulation of blood in the gums and by these means prevent and cure various diseases of the gums, including congested and receding gums

SCREENING-SHOVEL—O THIBAULT Box 548, Fall River, Mass In this instance the invention is an improvement in the class of shovels adapted for screening or sifting cinders coal, and other like commodities The shovel blade is formed of wrought iron or steel struck up in dies into the required form, and it may be cheaply and easily produced by means of cutting and shaping dies.

HINGE.—W. N BLANCHARD, 2215 Gaty Ave., East St. Louis, Ill The object here is to provide a hinge for general use, wherein the principal portion of the mechanism is arranged within the members to be hinged together, and means is provided in connection with the said mechanism for engagement by a cover, hood or blind to conceal the joint and the hinge

BELT FASTENER—J. EVANS, JR and JAMES EVANS, care of W. P Davis, 909 W North Temple St., Salt Lake City, Utah The invention pertains to fasteners in which a plate is provided with spaced fingers comprising, in general, the form of a club plate, the fingers being designed to be passed through holes adjacent to the meeting ends of the belt, the free ends of the fingers having means for preventing their accidental withdrawal

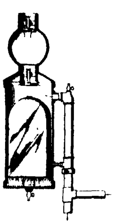
UNDERREAMER G A MONTGOMERY Box 76, Oilfields, Cal This invention is for use for enlarging a drill hole previously formed with an ordinary club bit in drilling for crude oil, and provides a large area of wearing surfaces between the cutters and their supporting elements, provides a construction in which these surfaces will be largely protected against the entrance of abrasive matter provides perfect seats for the cutters, makes provision for preventing the losing of the reamer cutters, promotes convenience in adjusting the reamer in position to be lowered into the well and, provides an underreamer the body of which is free from subjoints

UNDERREAMER FOR ENLARGING DRILL HOLES

CIGAR TUCK CUTTER G W BOWMAN, 409 S George St, York, Pa The general object in this case is to improve the construction of the retaining device and guard so as to be more flexible and engage the cigar when in position to be cut with just enough pressure as to hold it in co-operative relation with the cutters without danger of breaking the cigar which will effectually prevent the cigar being held by the operator while being cut

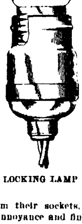
Heating and Lighting.

VALVE FOR VACUUM HEATING SYSTEMS A PORTER, Marquoketa Iowa An object of the inventor is to provide a steam heating system in which a vacuum is obtained by the condensation of steam air being prevented from entering the pipes by an air valve of special construction A further object is to provide means for permitting the escape of air when the steam pressure rises above atmospheric pressure



VALVE FOR VACUUM HEATING SYSTEMS

SELF LOCKING LAMP BULB—C BLASS, 312 Milford St Brooklyn, N Y This invention relates to electric lighting devices and has particular reference to a means for preventing the unauthorized removal of incandescent electric lamps from their sockets, a source of a great deal of annoyance and financial loss incident to the use of such lamps in public places Locking means co-operate between the lamp base and its socket, which operates automatic



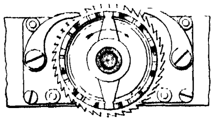
SELF LOCKING LAMP BULB.

ally to secure the parts together and which requires a special form of key for unlocking

LIQUID FUEL BURNER.—G E DENMAN, 3558 Custer St, Fruitvale, Cal This invention has reference more particularly to the class of device comprising an inner and an outer casing having independent inlets, one for fuel and the other for the compressed fluid, and a tip body secured to both of said casings and through which the liquid fluid is forced by means of compressed fluid.

OIL BURNER J A TRIMBLE and C H. MILLER, 5483 36th Ave, S E Portland, Ore The inventors have found in practice that the burner is very efficient, and the advantages obtained are due to heating the air and other gases before they enter the mixing chamber, so as to raise the temperature of the oil and make the same readily ignitible They thus accomplish a great saving of fuel, besides the uniform flame and even heating effect which the burner affords

CRANKING DEVICE.—T McCABE, Homestead, Pa This device is for use on gas or gasoline engines An object of the inventor is to provide a device especially adapted for use on automobiles and gasoline engines, the construction being such that the brakes must be set and the speed change lever must be in neutral position before the cranking can take place, and in the event of a back fire from the engine the crank will immediately disengage from the engine shaft The use of the device is intended also to prevent injury to a person while cranking an explosive engine



CRANKING DEVICE.

Household Utilities.

COOKING UTENSIL.—G W BLODGETT, 387 E Washington St, Portland, Ore The inventor's purpose is to provide a cover for the vessel which will prevent cooking without liquid in the vessel, and also condense the vapors formed during cooking and return the same to the vessel This is obtained by providing a cover formed of a series of superposed members having a large condensing surface

WASTE AND VENT SYSTEM C S C ROCK 204 W 140th St, New York, N Y The object here is to provide a system having a plumber's fitting designed to connect the soil pipe with the vent pipe and adapted to connect with bath tubs, sinks, water closets and other fixtures to be drained and vented, the arrangements being such that the plumber can readily assemble the parts and make the desired connections and that proper drainage and venting is insured

COOKER R W RYON 304 3rd St, S E, Washington D C An object in this case is to provide a device in which the cooking of such articles as sausages may be conducted while at the same time the heating of other articles, such as rolls, may be accomplished with means for permitting the flavor or essence of the sausages to be absorbed by the rolls

COMBINATION SUPPLY AND WASTE FIXTURE FOR LAVATORIES W A SPEAKMAN care of Speakman Supply and Pipe Co, Wilmington, Del Among the objects of this invention is to provide a fixture of unusually simple and neat design whereby the manipulation of the fixture is facilitated and the device rendered more reliable than previous ones. Further, to provide a water supply fixture for lavatories which is adapted to be used in connection with standard basins without alteration thereof

DISPENSING BOWL S A ADDIS, 944 Tiffany St Bronx, N Y, N Y This invention relates particularly to an improved bowl for dispensing sugar and other similar material, and has for an object to provide an improved structure which will allow the dispensing of measured quantities of sugar, and will prevent any wasting thereof

GAS RANGE BURNER.—E S ALLEN, 517 E 134th St, New York, N Y The improvement has reference to gas range burners, and the invention comprehends a burner provided with a valve, said valve being controllable by the position of a grid or spider associated with the burner for the purpose of supporting pans or other articles to be heated

Machines and Mechanical Devices.

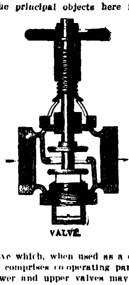
THREAD CUTTING MACHINE.—J A DOWD, P O Box 488, Fall River, Mass This invention refers to improvements in machines for cutting threads upon pipes, bars and the like, and for severing the pipes and bars at desired lengths The purpose is to provide a structure which will continually operate for threading a pipe, bar or the like and intermittently severing the pipe or bar into lengths

SHAPING ROLLS FOR HORSESHOE BARS —L. T. PAGE, Box 104, Wareham, Mass The invention provides means for mechanically creasing and partially punching the bars from which horseshoes are subsequently made; prevents the creeping or misregistering of the rolls with the bars and shoe-forming sections thereof, and reduces the friction offered by the bars to the rolls when passing therethrough

MIXING AND SIFTING MACHINE.—S. L. HARWOOD, Dublin, Ga This apparatus is for use in mixing and sifting fertilizing materials, and the machine will deliver a mixture which is very uniform, instead of discharging the fine ingredients of the mixture first and depositing the finer part of the mixture in the bottom of the sacks which receive it, an objection met heretofore in devices of this sort

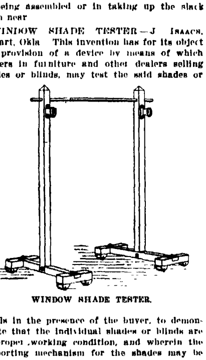
MARINE SAFETY DEVICE.—M. BOUCHET, 22 Rue Alphonse de Neuville, Paris, France. The inventor provides for increasing the buoyancy of the vessel at certain critical times when danger may accrue from undue pressure of water outside of the vessel, thus tending to crush the vessel inwardly, or from excessive air pressure inside of the vessel, having a tendency to disrupt the vessel or some portion thereof

VALVE.—A E CRUM, Mobile, Ala. This invention relates more particularly to a structure comprising a casing which permits the use of parts whereby a double acting or a single-acting valve construction is provided One of the principal objects here is to provide a valve which, when used as a double acting valve, comprises co-operating parts, whereby the lower and upper valves may be accurately adjusted on their seats when the valve is being assembled or in taking up the slack from wear



VALVE.

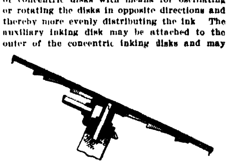
WINDOW SHADE TESTER.—J ISAACS, Hobart, Okla This invention has for its object the provision of a device by means of which dealers in furniture and other dealers selling shades or blinds, may test the said shades or blinds in the presence of the buyer, to demonstrate that the individual shades or blinds are in proper working condition, and wherein the supporting mechanism for the shades may be adjusted to any size of shade



WINDOW SHADE TESTER.

CLOTH WORKING MACHINE.—G H WIEMANN, 262 N. 6th St Brooklyn, N Y This machine winds or bolts quantities of cloth piled up in folds, each layer being separated from the layer above and below the same by sheets of paper or similar material The sheets of paper are continuously removed by the machine at the same time that the operation of winding the cloth is in progress

INKING DISK FOR PRINTING PRESSES.—F J ANTELOTTI, Norfolk, Va. This invention provides an auxiliary disk which may be used in connection with printing presses having inking mechanism consisting of a plurality of concentric disks with means for oscillating or rotating the disks in opposite directions and thereby more evenly distributing the ink The auxiliary inking disk may be attached to the outer of the concentric inking disks and may be spaced from the inner of said disks, thereby permitting the free movement of the inner disk A cover for the inner and outer inking disks serves as an inking disk itself, and when removed permits the inking to be done by the inner and outer concentric disks which form part of the normal structure of a machine.



INKING DISK FOR PRINTING PRESSES

LOOM SHUTTLE.—W H. WILSON, 7 Bedford St., New Bedford, Mass This shuttle is arranged to prevent the slack of the thread and consequent breaking thereof, and to prevent the thread from accidentally passing out of the eye at the end of the shuttle at the time the shuttle advances from the shuttle box toward the cloth, as at this time the thread is liable to curl up and break on further advance of the shuttle.

STRAP AND TAB FORMING MACHINE.—F METZENBACHER, care of W. H. Rich & Son, 708 Pacific Street, Brooklyn, N. Y. This machine is for use in the manufacture of umbrellas and other like purposes, and has reference more particularly to a machine of this class which comprise a strip forming mechanism, a cutter for severing the formed strip into lengths to produce straps or tabs, and means for simultaneously operating the strip forming mechanism and the cutter.

ALARM CLOCK ATTACHMENT.—R. P. PACKARD, 3717 6th Ave, Tacoma, Wash. The device is for use in connection with ordinary alarm clocks, and the aim thereof is to cause a lamp to be lighted when the alarm is rung. It comprises connections which are controlled by the position of the parts of the alarm mechanism and are so arranged further that the lamp can be caused to remain lighted so that the same can be kept in use after the alarm has ceased

SHUTTLE MACHINE EMBROIDERY FRAME.—H HOCHREUTENER, 708 Highpoint Ave, West Hoboken, N J This invention relates to improvements in frames for embroidery machines and to what are called section frames, and has for an object to provide improved structures in which no waste spaces are provided Means provide for the ready removal at times of the articles to be embroidered.

Prime Movers and Their Accessories.

INTERNAL COMBUSTION ENGINE.—N H SCHICKEL, 50 Garden St, Stamford, Conn. The object of the invention is to provide a feeding mechanism for internal combustion engines, such that the fluid to be fed will be displaced from the pumping chamber and transferred to the working cylinder in a substantially uncompressed state while the inlet port is open.

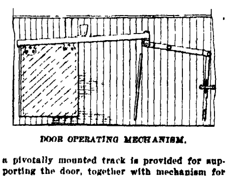
FLUID OPERATED ROTARY PRIME MOVER.—G H ALEXANDER and W G ROBINSON, respectively at Doe St, and 5 Elm Cottages, Falconer Road, Birmingham, England This invention relates to such fluid operated rotary prime movers as rotary internal combustion, steam, water and air engines, of the type in which a pair of cylinders and pistons is arranged parallel with each of a pair of axes mounted at an angle to each other, and the pistons are connected by suitable links with the members of a Hookes' or universal joint situated at the junction of the axes.

Railways and Their Accessories.

CONCRETE RAILWAY TIE.—R. T BAGBY, Whitney, N. C The object in this case is to provide a strong, inexpensive and stable tie which has large bearing areas in the road ballast for each of the rails, and the center of which area is substantially in alinement with the axis of the rail

GATE OPERATING MECHANISM.—J. E C. JACOBSEN, 29 Fourth Ave, Nyack, N Y., and C A V J SEGERSTEN, Nyack, N. Y This invention comprehends mechanism whereby a train in approaching a predetermined part of a track provided with gates will cause the gate to close automatically, will actuate lamps serving as alarms, and will retain the gates closed and the alarm active so long as the train is present, but when the train departs, the gates are automatically opened and the alarm rendered inactive.

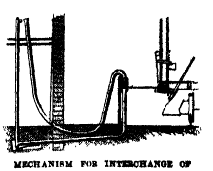
DOOR OPERATING MECHANISM.—W E HARRIS, care of Scott Mfg Co., Houston, Tex The object here is to provide mechanism especially adapted for freight car doors, wherein a pivotally mounted track is provided for supporting the door, together with mechanism for swinging the track, in order to utilize the weight of the door in opening and closing the same



DOOR OPERATING MECHANISM.

RAIL FASTENING.—L. FAUQUÉ, 52 Rue de Louviers, St-Germain-en-Laye (Seine-et-Oise), France. This invention insures the fixation of the rail by means of a device offering a resistance to the pulling stress always equal to the breaking strain of the metal of which it is constituted, allowing without any screw threading, a much more secure clamping than that of the screw spike and opposing any sinking of the rail on its supports, all these conditions being necessary for insuring the fixation of the rails of the wooden sleepers made of any species of wood.

MEANS FOR INTERCHANGE OF MESSAGES BETWEEN A STATION AND A MOVING CAR.—O. H. SMITH and J. L. SMITH, Stratford, Penn. Address the former. This invention relates to mechanism of the character set forth in a previous patent, No. 1,042,988, issued to these inventors. It provides a system of tubing leading from a railway station or other building in the proximity to a railway track, such tubing being adapted to deliver carriers to and from a car, such carriers being secured and deposited by the car as it moves along.



MECHANISM FOR INTERCHANGE OF MESSAGES.

Pertaining to Vehicles.

SPRING HUB.—W. H. LASSWELL, care Savoy Hotel, San Antonio, Tex. This hub is for use in automobiles and other vehicles, wherein yielding mechanism is provided within the hub, between the spindle and the wheel, for cushioning the vehicle against jar and jolting, and wherein yielding mechanism is concealed from view and protected from external injury and the entrance of dust and the like

SHOCK ABSORBER.—J. H NEDER, 2437 Center St, Baker City, Ore This absorber protects the arched springs of a vehicle from breakage due to sudden rebound of the springs as the vehicle passes over an obstruction or rough ground. The absorber is in the form of a helical spring readily attachable to the arched springs of the vehicle, which shall be noiseless.

RESILIENT TIRE.—R. E. LEAS, care of Nelson Bros, Luverne, Minn In this wheel the tread is movable relatively to the felly through the medium of ball bearings and springs, such parts being permanently inclosed, whereby they are kept free from entrance of dust and foreign matter Provision is made for maintaining the bearings in a constant state of lubrication

TIRE SPREADING DEVICE.—J. O. STEWART, 1201 First Ave, Spokane, Wash In the present patent the invention refers to improvements in tire spreading devices, and has for an object the provision of an improved structure for spreading a clincher tire structure so as to permit ready inspection of the interior thereof.

DOOR FOR AUTOMOBILES.—W. G. MINER, Sayler Park Station, Cincinnati, Ohio Doors of automobiles are ordinarily arranged to swing outward The inventor has devised an improvement by which doors are adapted to slide horizontally in guideways and pockets provided in the body of the vehicle, and he has provided such doors with spring attachments as a means or aid for closing them

WHIP HOLDER.—F F PROVAN, Marion, N. D. The invention comprises means for engaging the doubletree of the leading team or other fixed support and a holder proper for the whip hinged to the said means for swinging movement, together with means operable from a distance for swinging the holder, and other means for returning the holder to upright position, the holder having means for clamping a whip

Designs.

DESIGN FOR A GOBLET.—E. W. NEWTON, Chicago, Ill. This ornamental design for a goblet shows an article of rather tall form with a slim stem and plain base, the side view presenting a gracefully waved outline

---

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

WE wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject matter involved, or of the specialized, technical, or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

Washington, D. C.

Notes and Queries.

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12941) A. W. F. asks: Will you be kind enough to tell how to make a selenium cell, or, at least, what materials are used as contacts, and how? I have a piece of crystal selenium Do you think that I could make a cell with this piece sensitive enough to close a 150-ohm relay when the rays of an ordinary tungsten lamp are allowed to fall upon it? A. We would advise you that you cannot use a lump of selenium as a selenium cell. It is not sensitive to light The selenium must be treated to render it sensitive to light by heating for a long time. The cell is made by coating wires with the selenium so that the current may flow from one wire to the other through the sensitive coating. The whole process is described in the Scientific American and the Supplement in a number of papers We name Supplement Nos. 1430, 1881, 1882, 1883, 1897, 1719, 1912, and the Scientific American, Vol 100, No. 11, and Vol. 107, No. 21. We will send the nine papers for 90 cents. With these you will have full instructions how to proceed as well as full information upon the general subject of a selenium cell.

(12942) L. J. S. asks: 1. We have recently inquired if it is possible for you to inform us why vacuum bottles are covered inside with nitrate of silver. Does this process increase the efficiency of the bottle? Also, please inform us if there is any literature published on this subject? A. The vacuum bottles about which you inquire are coated with metallic silver and not with nitrate of silver This last is a white crystalline substance which is readily soluble in water and could not be made to coat glass The metallic silver is deposited upon the outer side of the inner bottle and the inner of the outer bottle so that there are two coatings of silver The object is to prevent the passage of heat A polished surface is a good reflector and poor absorber of heat Hence the outer surface of the bottle reflects most of the heat from the outside, and the second surface takes care of the rest. These bottles are the best known to preserve a liquid at a given temperature. Liquid air has been kept for a longer time in them than in any other way There is no special literature upon the subject 2. Kindly inform us if you know of any late literature published on the subject of water purification by means of ozone. A. You will find valuable papers upon ozone in the Scientific American, Vol. 107, No. 7, and Vol 109, No 1, also in the Supplement, Nos. 1832, 1895 and 1978, price ten cents each.

(12943) F. D. D. asks: This city is 5 hours, 42 minutes 40 seconds slow of Greenwich, therefore when it is noon at Greenwich it is 6 hours, 17 minutes, 20 seconds A. M. here. January 21st the sidereal time of mean noon at Greenwich is 20 hours, 0 minutes, 1 35 seconds. If at just 6 hours, 17 minutes, 20 seconds here I set my sidereal clock at 20 hours, 0 minutes, 1.35 seconds, will not that be the correct sidereal time at that moment here? It seems to me that it is correct, and a very easy way to set a sidereal clock, provided one is sure of his longitude A. If the difference of longitude is accurately known between your place and Greenwich, and you have the sidereal time of mean noon at Greenwich, you can set a sidereal clock to the sidereal time of your place as closely as the clock will allow You could not set the clock to the hundredth of a second. No clock can be set with that degree of accuracy.

(12944) A. J. R. asks: 1. Is it possible for ice to vary in temperature or density? A. Ice acts toward heat just like any other solid Raise it to its melting point and it turns to water, just as lead and tin melt when they are raised to their melting points. Cool it and it becomes colder just as any other stone or mineral will do If it is cooled it contracts and becomes denser, just as a piece of copper will do. A piece of ice lying in the open air when the thermometer stands at zero will itself be at zero in temperature. 2. Would there be any difference in the temperature of two cakes of ice brought to New York during weather never above 32 deg., one cake cut in the Hudson Bay country, the other in the Hudson River? Would one cake melt faster than the other if the weather got above 32 deg? A. If two cakes of ice were brought to New York from any great distance, when they reached this city they would both become of the temperature which the thermometer here indicates, the temperature of the air in New York. If one of these cakes had fewer air bubbles in it than the other, that cake might melt slower than the one which contained more air, but the difference would be due to the ice, not to the temperature. 3. Would a thermometer placed in the center of an iceberg indicate a greater degree of cold than if placed near the surface? A. Ice in contact with air or water which is warmer than 32 deg Fahr. will be at 32 deg., the melting point of ice. It cannot be made hotter than 32 degrees without turning to water. So long as it is ice it is not hotter than 32 deg. Fahr., no matter what it is in contact with. An iceberg floating in water will be at 32 degrees if the water is not colder than 32 degrees, since the ice is fresh and not salt. 4. Assuming a deep river or lake to be frozen to a depth of 32 inches, with the weather at zero, would the ice have a gradually higher temperature of one degree to the inch from 0 degree at the surface to 32 degrees at the bottom? A. Ice 32 inches thick, when the air on the top is at 0 degree and the water below is at 32 degrees, will change its temperature from top to bottom about 1 degree per inch, as you state. 5. If the weather remained at exactly 32 degrees all winter, would the ice in a pond increase in thickness from day to day, or would only a thin coat of ice form on the surface? A. Ice could not become very thick if the air above did not become colder than 32 degrees at any time. 6. Can a cake of ice—without melting—lower the temperature of an article placed on top of or adjacent to it? A. Ice cannot cool anything without melting, excepting the ice is colder than 32 degrees and the article in contact with the ice is already as cold as 32 degrees. Ice at 32 degrees in contact with an article which is above 32 degrees cannot cool that article without itself melting An ice box in Summer is not itself cooled by the ice unless the ice melts.

(12945) O. W. F. asks: I would like to know why telephone wires do not sing alike when the wind blows and when it does not Sometimes they make quite a great deal of racket when the wind is not blowing, and again they do not make any. A. A wire strung through the air sings, or gives a musical sound, when the wind blows over it, and the friction of the air sets the wire into vibration in the same manner in which a violin string is vibrated by the friction of the bow It is not necessary that the wind should be blowing hard for this effect to be produced, indeed, the tones are softer when a gentle breeze draws over the wires Nor is it necessary that the sound should be produced at the place where it is heard It may be quite a distance away where the breeze is rubbing over the wires, since sound is carried with a high velocity over metals We think this sound is always due to the friction of the air across the wires. The action is like that of the Æolian harp.

(12946) H. D. asks: I wish to know the exact effect of centrifugal force in connection with the ocean tides which rise on the side of the earth opposite from the moon I find no reference to this subject in popular astronomies or in the textbooks I have seen As the center of gravity between earth and moon lies some 3,000 miles below the earth's surface, it follows that about 5,000 miles is the radius of a circle described by an imaginary point on the earth's surface every lunar month It also follows that every part of the sea is more or less affected by the centrifugal force resulting from this slow revolution and affected by it every day. Is not the opposite tide to a large extent the result of this force? What books treat of the matter? A We have never seen any calculations of the centrifugal force developed in the rotation of the side of the earth opposite the moon and its effect upon the waters of the ocean in the tide on that side of the earth It can be but slight The tide on the side opposite the moon is due to the fact that the attraction of the moon on the solid earth is greater than the attraction upon the water on that side of the earth The center of gravity of the earth is about 60 radii of the earth from the moon, while the water of the remote side is 61 radii distant from the moon The attraction upon the solid earth, as compared with that upon the water, is therefore $\left(\frac{61}{60}\right)^2$ which is 1 033 + Thus the attraction upon the earth is about 3 3 per cent less than it is upon the remote water. A similar calculation for the side of the earth toward the moon gives a result that the tide-raising force on the side toward the moon is about 3 4 per cent of gravity. Centrifugal force plays its part in the formation of the tides, but it is not the larger factor in the problem.

(12947) C. S. C. asks: Do you know of any metal or substance of any kind that the lines, magnetic lines, from a permanent magnet will not penetrate? Some material, if a permanent magnet is placed under it and iron filings above, that the filings will not be attracted A. There is no material known through which lines of magnetic force will not pass. The only way in which a magnet can be screened is to place it in an iron box. The iron affords a much easier path for the magnetic lines so that they do not emerge into the air on the inside This forms what is called a magnetic screen.

(12948) R. A. D. asks: I note your reply to Query 12893 on January 3d, 1914. May I ask whether there is no more modern theory of the behavior of gaseous molecules than that of their being perfectly elastic bodies which collide and rebound without loss of energy by virtue of this property of perfect elasticity? If the pressure that a gas exerts upon the walls of a containing vessel is due to the velocity of the mass of the molecule, as in the case of a sensible missile, why is not the velocity of the molecule lessened with each impact, and consequently the pressure, even though the temperature remains constant? Briefly, is not the hypothesis of perfect elasticity merely a convenient cover for our ignorance of the specific nature of the phenomena in question? Is there accessible any coherent speculation on the subject? A. The well-nigh universal acceptance of the theory of perfect elasticity of gas molecules is the basis for our statement in Query 12893, which you question. Since your letter was received we have gone through the latest works by the best authors on this subject and find our statement in varying terms in them all Gas pressure is regarded as simply the beating of the molecules against the walls of the vessel and each other One states it that the molecules rebound with "undiminished velocity," which is just the same as saying that they possess perfect elasticity Another says, "This theory is held because it enables all the laws of gases to be readily explained" There is no disagreement among physicists on this point So we are not able to refer you to any "coherent speculation" about the matter.

(12949) O. O. B. asks: In Millikan & Gale's "Physics" there is the following experiment under the topic "Heat of Fusion" In a mixture of salt water pour snow or cracked ice and stir vigorously until the temperature reaches a point 10 or 12 degrees below zero Cent. Then into this place a test tube containing pure water and a thermometer Note that the temperature of the water in the test tube will fall as much as 10 or 12 degrees below zero Cent and not freeze, but as soon as you drop into the test tube a small piece of ice or stir the thermometer, the temperature will fall to zero Cent. and will remain there until the water is all frozen. Please explain why the water in the test tube does not begin to freeze as soon as it gets to zero Cent Is it because water will not freeze at zero Cent provided it is kept perfectly still? A The experiment which you describe is one which illustrates "undercooling" A liquid which has a definite freezing point can be cooled several degrees below that point without freezing if it is kept still so that there is no jarring or motion of the liquid, or if it is covered with a layer of oil But if it be jarred or a shock be given to it by dropping a crystal of the same substance into the liquid, it will crystallize at once. Sodium sulphate dissolved by heat is often used for the experiment, although water will answer very well. The undercooled liquid is in unstable equilibrium, and the molecular attractions are equal in all directions, but when the liquid is stirred the equilibrium is upset, and the molecules then jump into their places in the solid form which their temperature requires

(12950) J. W. McC. asks: I am anxious to get in touch with some schools that have divided, or rather segregated, the boys and girls in the physics work We are doing the work on this line this year, but have not been able to find a suitable text for the girls This is what I am after Any information will be appreciated A We do not know any schools in which the girls are taught physics in classes separated from the boys. Physics is usually taught as a branch of mathematics in high schools and most colleges, and the subject is divested of most of its interest for young people for this reason A textbook based upon the experiment and not upon the formula is much to be desired One appeared this year which is very attractively gotten up by Millikan & Gale, which we send for $1 40 postpaid It is called "A First Course in Physics," and is almost wholly descriptive No similar college textbook has appeared

(12951) T. A. B. asks. I had a question asked me as to what was in a thermometer I said that mercury and alcohol were used but some said that quinine and some other liquid were in them I would like to have you tell me what is used in them A. The liquids used for filling thermometers are mercury and alcohol Sometimes the alcohol is colored red with a dye. Quinine is not a liquid, but is dissolved in water, and water cannot be used for a thermometer in any place where it would freeze, for the reason that it expands when it freezes and bursts the vessel Alcohol does not freeze till it is cooled 200 deg Fahr below zero, and the lowest temperature on the earth is not 100 degrees below zero Hence alcohol is used in all places where the temperature falls below —40 degrees, at which point mercury freezes Mercury may freeze in a thermometer without breaking it, since mercury contracts on freezing But it will not indicate temperature correctly after freezing because it contracts differently in the solid from what it does in the liquid condition

(12952) If the correspondent from Fairmont, W Va., will give us his name, we will be glad to give him the information asked for It is impossible for us to reply to unsigned communications

(12953) If H. T. will send his name and address we will gladly answer his question But no attention can be paid to unsigned queries In this case the answer would be by mail, since the answer has no interest excepting for himself

(12954) J T. P. asks. Being a reader of your paper, and noting that you maintain a column in which you answer questions pertaining to scientific matters, I should like to know if you can give me a formula that will enable me to soften printer's ink What I wish this information for is, to transfer printed pictures to paper, cardboard, etc. Perhaps you can tell me some method by which I can do this work. My biggest trouble seems to be in finding a solvent that will not destroy the colors in the print. I would also like to get a formula for sensitizing paper, etc., such as is used in photography. I have the blue-print formula, but am in need of something that will give me a black and white, or a brown and white print I understand that you publish a book of formulas, etc. I will be pleased to learn the price, etc I consider Notes and Queries worth the price of Scientific American alone I have received some valuable hints therein A. A method of transferring newspaper pictures is given in our "Scientific American Cyclopedia of Formulas" price $5, as follows. In 1 pint of hot water dissolve 1½ drams of common yellow soap, and when nearly cold add 3¼ fluid ounces of spirits of turpentine Shake the mixture thoroughly. Apply this fluid liberally to the surface of the print with a sponge or soft brush, being careful not to smear the ink which soon becomes soft Then dampen well the plain paper upon which the transfer is to be made, and apply it smoothly to the print with moderate pressure for about one minute On separating them a reversed copy of the print will be found upon the paper The Cyclopedia contains many other processes for transferring Information on the subject will also be found in our Supplement Nos 1122, 1141 and 1094, price 10 cents each mailed

(12955) F. Z. asks Wanting to use old negatives, is there some cold-water formula for removing the film from the glass that is non-injurious to the hands? A There is no efficient cold-water method for dissolving gelatine film from old negatives Boiling them in water will dissolve the film, but the best way to get it off is by soaking in strong nitric acid This can be done without injury to the hands Handle the plates with thin slips of wood sharpened to an edge, which nitric acid does not readily affect The glasses can be taken out of the acid with these pieces of wood and dropped into water to wash off the acid The next wash should be of potash, and then a final bath in hot water will complete the cleaning For the wooden slips we use pieces of cigar boxes

(12956) F. A. L. asks: During a discussion of the relative merits of gas and electricity for heating, a very heated argument arose as to the scientific reason, or I might say the theoretical reason, of the non-luminosity of a Bunsen flame. It was agreed to submit the question to you for explanation, as all of us are readers of your valuable paper Your decision will settle a much-vexed question A The low luminosity of a Bunsen flame is due to the more complete combustion of the gas in the flame by the oxygen of the air which is mixed with the gas before it comes to the flame and is ignited In an ordinary flat flame the air comes into contact with the gas at the base of the flame and there you will see a blue or nearly colorless flame Here the heat is sufficiently high to reduce the gas to solid carbon particles and to heat these so that they become luminous The oxygen of the air in contact with the flame above now burns the solid carbon, and changes it to carbon dioxide, after which the gas diffuses into the surrounding air. The temperature of a Bunsen flame is higher than of a luminous flame, since the combustion is more perfect and the heat is confined to a smaller area The temperature of a luminous flame is that of white heat of the solid carbon particles It is given somewhat differently by different authorities, but it may be safely taken at 2 000 deg Fahr., or perhaps at 2 200 deg Fahr The temperature of the Bunsen flame may be taken at about 2,000 deg Fahr This is the figure of Prof Vivian Lewes, as quoted in Ganot

(12957) B. asks 1 Can you tell me whether the relation between heat, light and sound is such that if a metal bar were set in vibration and the vibration frequencies gradually increased, sound, heat and light would be produced in turn? A The mode of vibration in sound is that the material which is in vibration moves backward and forward in the same direction as the wave is moving The motion of the vibrations in heat and light are across the direction in which the wave is moving A sound wave cannot affect the eye nor can heat and light waves affect the ear 2 Are not light waves shorter than heat waves, and in heat are the waves shorter in higher temperatures? A Heat and light are the same in kind, only differing in degree In the light spectrum, the longest waves which are visible to the eye are three hundred ten-millionths of an inch long, and the shortest are one hundred and fifty-six ten-millionths of an inch long Heat waves extend through the greater part of the light spectrum, and far below it, thus having a greater range Within the range which the eye can perceive, if a train of waves enters the eye we see by means of it but if it struck the skin we should feel heat and not light The same waves affect the person differently according to the nerve they impinge upon If they strike the optic nerve they are transformed into light, if they strike a nerve which can feel heat they are perceived as heat Light waves are longest in the red of the spectrum and shortest in the violet Heat waves extend below the red for a long distance, increasing in length downward below the red heat The higher temperatures have the shorter waves 3 Mathematically there would be no vacuum created in a Torricellian tube if the tube were 50 centimeters in length Is that correct? A The vacuum in a Torricellian tube is formed when the tube is so long that the pressure of the air is not able to support the mercury to the top of it At the sea level and in good weather the mercury will be held up to 30 inches, or 76 centimeters. If the tube is shorter than that the mercury will be held up to the top if longer the mercury will not fill the tube and the space above the mercury is called a Torricellian vacuum. It contains vapor of mercury.

NEW BOOKS, ETC.

WAR TIME IN MANILA. By Rear-Admiral Bradley A Fiske, U.S N., of the U S S "Petrel" and "Monadnock" during the War. 275 pp, numerous half-tone illustrations. Boston: Richard G. Badger, The Gorham Press.

It is many years since Dewey sailed into Manila Bay and fought the memorable action with the Spanish fleet, but it is not so long ago that the more intimate incidents of that action and of the events succeeding as told by a personal eyewitness fail to have a fascinating interest for the reader Much has been written about the naval and military campaign in the Philippine Islands, but we doubt if any work has appeared which carries such a personal and intimate touch as the simply and very graphically written account contained in this volume

Many people have wondered how the fighting man feels in the moments preceding his entry into battle and this volume gives us here and there an illuminating insight to the psychological side of this interesting question as note the following describing the night hours immediately preceding the battle of Manila Bay

"I found the wardroom absolutely dark Then I felt my way to my own room and lay down on my bunk The deck above my head was distant about two feet and I thought how very flat I would be squashed out against that deck if a torpedo exploded under the ship" Fiske's position during the engagement was probably one of the best points of vantage from which to view the battle with Admiral Montojo s little fleet of gunboats Says he "There was not even a conning tower on the 'Petrel,' so I had rigged up a platform on the foremast about forty-five feet up, where I could sit with my stadimeter above smoke and measure the range of the enemy and inform the captain of whatever important incidents or movements my clearer view might enable me to see" Says the writer About the decks of the 'Petrel' things were entirely different from what I had expected I had seen many pictures of battles and expected great excitement I did not see any excitement whatever The men seemed to me to be laboring under an intense strain and to be keyed up to the highest pitch, but to be quiet and under complete self-control, and to be doing the work of handling the guns and ammunition with that mechanical precision which is the result we all hope to get from drill Admiral Fiske criticises the Spaniards for not putting their fleet under the batteries of Manila, where four powerful modern 9 2-inch guns were mounted, guns which if properly handled, could have sunk the whole of the American fleet "Any one of these guns would have sunk our vessel or disabled the other ships" The work deals in the most interesting and illuminating way not merely with the sea-fight itself but with the operations, naval and military, which followed Dewey's victory Anyone who wishes to get an intimate view of naval life as seen from the standpoint of an unusually intelligent and observant naval officer who has the gift of looking below the surface of things and analyzing what he sees with a philosophical mind will do well to purchase this most interesting work

MACHINERY'S HANDBOOK. For Machine Shop and Draughting Room. A Reference Book on Machine Design and Shop Practice for the Mechanical Engineer, Toolmaker and Machinist New York The Industrial Press, 1914 12mo, 1400 pp, illustrated. Price, $5

Machinery has put out a reference book that is good to the eye and helpful to the hand It embodies the best of a twenty years' accumulation of material with gleanings of important data from hundreds of sources The work collects and systematizes the established principles and practice in the design construction and operation of machinery There are tables - mathematical, logarithmic and trigonometrical, data dealing with strength of materials, with gages with keys and keyways with shafting and with gearing, formulæ for springs, block brakes rope drums and riveted joints This is but mere random mention It would be hard indeed to find any essential phase of machine design or construction that has been overlooked or slighted The pages are lavish of diagram and clear as to meaning Among operations may be cited grinding polishing, broaching, testing for hardness die-casting, forging welding and etching This list will convey some idea of the versatility of treatment The primary principles of geometry, and of mechanics, are concisely set forth the properties of air, water and heat are considered, there is a digest of the patent regulations and an index which is the open sesame to the treasure of the volume The work easily takes the place of many smaller and less authoritative books that cumber the shelf of the mechanical engineer, the draughtsman and the machinist

ARTIFICIAL PARTHENOGENESIS AND FERTILIZATION By Jacques Loeb, Member of the Rockefeller Institute for Medical Research. Originally translated from the German by W. O Rodman King, B A. Chicago: The University of Chicago Press, 1913. 8vo.; 312 pp. Price, $2.50 net. Postage, 18 cents.

This is an enlargement of the work that in 1909 set the world talking—a description of the experiments that led the press to announce that the artificial production of life was an accomplished fact The actual extent of the achievement is of course, the artificial fertilization of the egg, dispensing with the assistance of the spermatozoon; and in using these physico-chemical agencies the result is limited to fertilization and maturation, the hereditary features usually conveyed by the male cell naturally being absent This, however is glory enough for the time being It is but the absorbing preface to what is practically a new science Loeb's first two chapters set forth the present status of this science in language readily understood by any educated person The behavior of the egg under the chemical stimulant is closely observed, and deductions as to its changes under the influence of the spermatozoon are interestingly drawn A suggestion laymen are to-day closely following the development even of abstruse and specialized science, subjects that were yesterday closed to popular discussion are to-day topics of general conversation Why do not scientists more generally include in their works a glossary of the terms used? This would add greatly to the satisfaction of the general reader, promote the sale of such works, and forward the cause of education

HARPER'S BEGINNING ELECTRICITY. By Don Cameron Shafer. New York: Harper & Brothers, 1913. 8vo.; 275 pp.; fully illustrated. Price, $1 net.

HARPER'S WIRELESS BOOK. How to Use Wireless Electricity in Telegraphing, Telephoning, and the Transmission of Power. By A. Hyatt Verrill. New York Harper & Brothers, 1913. 8vo; 185 pp.; fully illustrated. Price, $1 net.

These two books, uniform in size, address themselves to the young student. The first forms an introduction to the general subject of electricity. Written for "the real beginner," the text shows extreme care in the selection and presentation of the various phases of a complex subject. What we know about electricity is sketched in the first chapter, from a talk on the behavior of electrical energy we pass to simple experiments in static electricity, and to galvanic action. Batteries, the electric circuit, magnetism, and their application in modern devices are but a few of the things explained. The second volume is a brightly written manual of wireless. The principles, operation, and construction of wireless transmission are lucidly set forth with the aid of lavish illustration The chapter on the establishment of a station deals with site, construction of aerials insulating and ground connections The student is wisely taught to make his own instruments—for in no other way is such a grasp of essentials obtained as by making a thing throughout

SUSPENSION BRIDGES AND CANTILEVERS. Their Economic Proportions and Limiting Spans. By D B. Steinman, C.E., Ph D New York D. Van Nostrand Company, 1913 16mo.; 185 pp. Price, 50 cents

The entrance of this little work into a second edition has given opportunity for its revision The analytical studies of the relative merits of suspension and cantilever types remain the same but there are modifications in nomenclature and definitions which allow the distinctions between theoretical and practical limits of span to be more closely drawn All alterations are in the interests of precision, the bibliographies have been extended and references to articles appearing since the publication of the first edition have been added Four folding plates illustrate the described designs

THE "WELLCOME" PHOTOGRAPHIC EXPOSURE RECORD AND DIARY. 1914. New York. Burroughs, Wellcome & Co Price, 50 cents.

The Record is a neat little snap-flap pocket-book with processes and tables, a number of blank pages are ruled for recording details of negative exposures, with space for an index. Diary and memoranda pages follow A unique feature of the book is the circular sliding scale affixed to the inside back cover, which gives the correct exposure in seconds or fractions of a second. The issue of a special United States edition is a point that will appeal to American photographers

SOLVENTS, OILS, GUMS, WAXES AND ALLIED SUBSTANCES. By Frederic S Hyde, Ph B. New York· D. Van Nostrand Company, 1913. 12mo.; 176 pp. Price, $2 net.

The factory chemist will find in this condensed reference work descriptions of the organic products of commerce, with their chemical make-up, a hint as to the process of obtaining them, and details of their appearance, qualities, and chief uses. The products are grouped under general heads such as terpene bodies, soaps, fatty acids, carbohydrates, etc Any difficulty in finding a required substance, due to ignorance of the classification under which it comes, is obviated by a full index

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC AND PHOTOGRAPHER'S DAILY COMPANION 1914. Edited by George E. Brown, F.I.C. Fifty-third issue. New York: George Murphy, Inc. Price, paper, 50 cents; cloth, $1.

A triumph of compact corpulence, the annual comes to us this year with its usual quota of directories, formulæ and papers. Since the advertisements are responsible for more than two thirds of the volume's bulk, we may be pardoned for mentioning them first They are not only advertisements—they are divertisements—good, bad, and indifferent, but mostly good. Their photographic reproductions and the wealth of old and new apparatus they offer will hold the camera operator's attention as much as the text proper. The latter, in addition to the almanac, tables, and processes, numbers among many new features a glossary of photographical terms, with foreign equivalents; and reproductions of incorrectly exposed and developed negatives, which point their moral more effectively than pages of dry warning. The progress of the past year is summarized, and helpful hints and articles abound.

HANDBOOK ON SANITATION. A Manual of Theoretical and Practical Sanitation. By George M. Price, M.D. New York: John Wiley & Sons, Inc., 1913. 12mo.; 353 pp.; 25 illustrations. Price, $1.50 net.

This handbook, first published twelve years ago, is in its rewritten form to be unqualifiedly commended to health-inspectors and physicians. It is used as a school and college text-book, and might be very profitably studied by the general public It covers soil and sites, air, ventilation, heating, water supply, sewage disposal, and plumbing These constitute the material of the first part The second is devoted to sanitary practice, and deals with the problems of housing, of trades and occupations, and of disinfection. The third part relates to sanitary inspection as a profession and gives important information on civil service examinations, with many useful calculations and tables. The style is condensed, but practical

THE WONDERS OF WIRELESS TELEGRAPHY, Explained in Simple Terms for the Non-Technical Reader. By J. A. Fleming, M A, D Sc., F R S New York: E. S. Gorham, 1913. 12mo.; 279 pp.; illustrated. Price, $1.40.

The plethora of cheap works on wireless telegraphy, addressed to non-technical readers, bears witness to the wide-spread interest in this means of communication Our author condemns many of the popular handbooks on this subject as giving "insufficient explanations of the physical processes involved" The general reader will find this work dealing at greater length and detail with the phases of radiotelegraphy than do the cheap books to which objection is made It presents theories of the ether, electricity, and electrons, gives the known facts of electric oscillations and waves, describes wireless apparatus and its operation fully, and refers to wireless telephony and the utilization of electromagnetic waves Pictorial illustrations are not spared wherever their inclusion is necessary to a quick grasp of principles.

MECHANICS FOR BUILDERS. Part I. By Edward L. Bates and Frederick Charlesworth. Longmans, Green & Co., 1913. 12mo.; 201 pp, with diagrams. Price, $1 net.

Students of building construction who desire to perfect themselves in the principles of form and design are generally required to wade through the whole subject of applied mechanics This textbook selects from the larger study such subjects as bear directly upon building problems. Volume 1 presents a first-year course of great flexibility, in which is given a thorough grounding in strength of materials and theory of structure

PRACTICAL HAND BOOK OF GAS, OIL, AND STEAM ENGINES. Stationary, Marine, Traction. By John B. Rathbun. Chicago: Charles C. Thompson Company, 1913. 8vo, 370 pp.; illustrated. Price, silk cloth, $1; flexible leather, $1.50.

The work exhibits a thorough knowledge and an ability to so express the knowledge as to make it available for the layman It deals with the construction, operation, and repair of all kinds of engines, with the various parts in detail, and with the different kinds of fuel.

THE AUTOMOBILE BLUE BOOK. 1913. Volume II. New England and Maritime Provinces. New York: The Automobile Blue Book Publishing Company. Cloth; 5¼ x 9⅜ inches; 1100 pp.; with several maps. Price, $2.50

This handy guide, or touring handbook, hardly needs an introduction Covering the motor routes of the New England section and the Atlantic Provinces of Canada, with connecting extensions into adjoining states and provinces, with the care, detail and completeness that have characterize this work in the past the book should most certainly be included as part of the equipment of all autoists The sections have been systematically arranged for the convenience of the user and the routes shown in graphic detail on the large index map At the beginning of each route the principal points of interest along the way are outlined Coupled with this, is a complete and comprehensive index covering over 20 pages, that makes the matter of locating a city or town a very simple thing

BEYOND THE ATOM By John Cox, M.A. Cambridge· At the University Press. New York. G. P. Putnam's Sons, 1913.

Here we have a popular account of the new theories of matter written by a man who has been associated with Prof Rutherford, and has therefore been privileged to witness at close quarters and discuss from day to day discoveries which have radically changed scientific conceptions within the last decade Mr Cox begins by introducing us to the atom in the seventies, but before contrasting it with the new atom, he discloses the mechanism whereby the new atom was discovered and its phenomena studied Hence we find chapters on the vacuum tube, the new rays, the new substances, disintegration, the objective reality of molecules, before the new conception of matter is really presented. The book may be strongly recommended as a trustworthy and simple presentation of one of the most wonderful series of investigations to be found in the whole history of science.

PRACTICAL PATTERN MAKING. By F. W. Garros. Second edition, revised and enlarged. New York: The Norman W. Henley Publishing Company, 1913. Price, $2.

This is the second edition of a very useful book written by a pattern-maker of thirty years experience. He describes not merely the principles of pattern making, but also the materials and tools required in this most important art. A valuable portion of the book is to be found in the illustrated examples of pattern work in wood, of metal pattern work and plate work, vibrator and stripping plates Specific instructions for plaster work are also given.

A SURVEY OF THE WOMAN PROBLEM. By Rosa Mayreder. New York: George H. Doran & Co., 1913.

Rosa Mayreder's book attracted widespread attention throughout the German Empire soon after its appearance Written by a forceful woman in a forceful style, it is here presented to the reader in an excellent translation by Mr. Herman Scheffauer. The woman problem is considered from the economic, social and ethical-psychological standpoint. It must be confessed that the author makes the most of the present rather confused status of sex psychology. She places in sharp contrast the diametrically opposed views on the intellectual and emotional capacity of woman uttered by the most distinguished men in history —a very effective weapon She takes rather too seriously, however, the utterances of Lombroso and Weininger and similar men whose scientific pretensions have long since been riddled. In these days of feminism, equal suffrage and the general movement on behalf of women, a book such as that of Rosa Mayreder should be welcomed. It is polemic, but eminently sane.

DIE WASSERDRACHEN. Ein Beitrag zur baulichen Entwicklung der Flugmaschine von Joseph Hofmann, Preussischer Regierungsbaumeister und Kaiserlicher Regierungsrat a D. in Genf. (Luftfahrtzeugbau und -Führung, Bd. XIV.) VI und 82 Seiten 8°. Mit 57 Abbildungen im Text und 2 Tafeln. Munich: Oldenbourg, 1913.

In this book Mr. Hofmann, one of the pioneers in aerial navigation in Germany, discusses the problems of the hydro-aeroplane in a way that will be appreciated at its true worth by the student of heavier-than-air flight While the discussion is essentially mathematical, the mathematics are of a simple algebraic kind that anyone who has passed through a high school can easily understand The book is by far the best treatise on the designing and flying of a hydro-aeroplane under various conditions that we have thus far seen. It constitutes one of the series of excellent handbooks on aerial navigation edited by Capt Neumann

LEITFADEN DER DRAHTLOSEN TELEGRAPHIE FÜR DIE LUFTFAHRT von Max Dieckmann, Privatdozent für reine und angewandte Physik an der Technischen Hochschule München. (Luftfahrtzeugbau und -Führung Bd. XIII.) X u. 214 Seiten 8° mit 150 Textabbildungen. Munich. Oldenbourg, 1913.

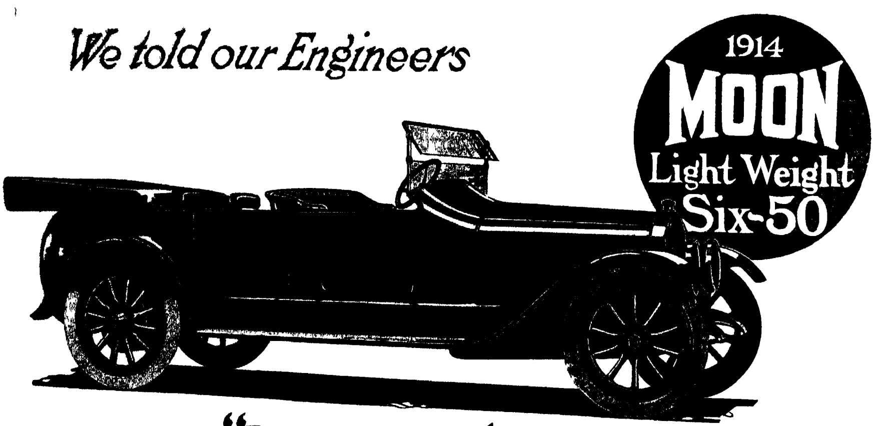
The author of a simply worded book on so highly technical a subject as wireless telegraphy finds himself in an awkward position He cannot take anything for granted, for which reason he must explain at considerable length conceptions and terms which form part of the elementary intellectual equipment of every wireless operator Accordingly, the author of this book was constrained to discuss in his introductory chapters the atomistic conception of electricity, direct currents, closed and open oscillatory circuits, radiation, etc. This he has done with rare lucidity, with the result that the following portions of his book, which deal properly with wireless telegraphy and its application to the aeroplane, should be thoroughly understandable by any educated person.

ACCOUNTING. Practice and Procedure. By Arthur Lowes Dickinson, M.A. New York: The Ronald Press Company, 1914. 8vo.; 315 pp.

Accounting is a highly important concomitant of business—particularly of big business. Yet, as the author points out, as a profession it is at a disadvantage in comparison with that of law, since its often momentous decisions are arrived at privately, and the world at large never hears of its solutions. After devoting a chapter to bookkeeping, the succeeding seven chapters take up the income account and the balance sheet. Later we consider some problems in cost accounting, and finally the responsibilities of the public accountant are dealt with. An appendix contains sections of the English laws relating to auditing, consolidation, prospectuses, etc., and the form of balance sheet statement prescribed by the Interstate Commerce Commission for steam roads. The New York form for the annual statements of life insurance companies is also given.

COAL. Its Origin, Method of Working, and Preparation for Market. By Francis H. Wilson, M. Inst. M.E. New York Isaac Pitman & Sons. 8vo.; 129 pp.; illustrated. Price, 75 cents.

We told our Engineers



"Design the Best Light Weight Six"

ℭ They said, "how about costs?"

ℭ We said, "that's up to you—go ahead with quality as your standard—we'll talk about cost when the car is designed."

ℭ This leeway was just what they wanted—it started them off with true engineering enthusiasm. There never was a "big" engineer who (like an architect) didn't hate cost-hamper when he was trying to design for quality.

ℭ They used their leeway to the limit—and when they got through we OK'd the designs, suggestions and specifications without snipping off a penny of legitimate, quality-ensuring expenditure.

ℭ Here are some of the results of this "open policy" of motor car designing

First—The motor is built by the Continental Mfg Co (our design)—with the Continental manufacturing standards of finish, smoothness and quietness. Weight but 590 pounds.

Second—All cars equipped with *Delco* Starting, Lighting and Automatic Ignition System. The system that has stood the test of three years.

Third—Timken Bearings

Fourth—Warner four speeds ahead and reverse transmission, with direct on third, and mounted on Timken Bearings

Fifth—Spicer Joints, Warner Steering Gear and Timken Bearings Motor driven tire pump

Sixth—Specially, originally and beautifully designed Moon bodies

A Genuine Light Weight Six

—weighs no more and costs no more to operate than a Four of the some power Yet—it is no underweight skeleton or miniature of a car—big roomy and heavy enough to ensure stamina—a car that stands up.

The Moon Dealer in Your City

will be glad to demonstrate Moon quality If there is no Moon man there, write us You'll never know *all* the reasons why a Light Weight Six is the car for you until you've seen the Moon

ELECTRENE FIRE EXTINGUISHERS

are without question the most efficient and convenient that are manufactured today.

We are ready to enter into open test and competition with any Extinguisher of the same liquid capacity; and that is the surest proof that **Electrene** has points and features not possessed by any other.

You don't have to pump, which is a twofold advantage—it takes no energy and because of this your "aim" is sure.

When large Corporations (whose watchword is Safety First) test an extinguisher for years and adopt it; enough is said.

The New York **Interborough Rapid Transit System's Engineering Department** has officially adopted the **Electrene** Fire Extinguisher and has placed a big order. This after testing for a period of about two years

The **Electrene** Fire Extinguisher is standard in the New York Fire Department

Electrene is in a class by itself. As to sizes. one quart size is for house, automobile and general private use. One and one-half quart size for Railroads, Factories, Fire Departments, Hotels, Office Buildings, etc , etc

Among the Big Users are:

The Brooklyn Rapid Transit Company which has placed 1,000 ELECTRENE Fire Extinguishers on its Electric Cars.

The new Biltmore and the Waldorf-Astoria with 300 ELECTRENE Fire Extinguishers in their equipment.

The New York Central which has equipped its electric locomotives with ELECTRENE Fire Extinguishers.

The Southern Pacific R. R. has just reordered a number of ELECTRENE Fire Extinguishers.

The Standard Oil Co. of N. J. has given another reorder after two years use.

The Consolidated Electric Light and Power Co. of Baltimore has just reordered 100 machines of the 1½ quart size.

The Gold Medal and Diploma of Merit at the International Exhibition of Safety and Sanitation

held in the Grand Central Palace, New York, December 11th to 20th, is a clinching proof of its excellence — if further proof is necessary.

Send for our illustrated booklet describing the **Electrene** Extinguisher in detail—what it is—what it will do—and what it actually has done. Find out about its convenient sizes

ELECTRENE COMPANY
Whitehall Building New York

Navigating Lights for the Panama Canal

(*Concluded from page 206.*)

portant light stations as the Ambrose channel to New York and the Delaware River channel to Philadelphia. As the light burns continuously, it is true that considerable gas is wasted, but the cost of the gas wasted during daylight hours is insignificant compared with the pay of an attendant; and, besides, these buoys are often placed on dangerous shoals and reefs which are unapproachable except in calm weather.

Mr. Dalen has also invented a valve used in the A. G. A. system, operated by sunlight for automatically turning the gas off during bright hours and turning it on again in fog and darkness, but so far it has not been practicable to install these sunvalves on buoys. On stationary light towers, however, they have proven a decided success. That the sunvalve is not affected by the temperature of the air is demonstrated by the fact that the Lighthouse Bureau has installed them on lights in the icy waters of northern Alaska and in the tropical seas of Hawaii and the Philippines with equal success. Its construction and operation are based upon the well-known physical law, that a dull dark surface will absorb more heat when exposed to light than one with a bright and shining surface. The Dalen sunvalve shown in section in Fig. 5 comprises a base having gas inlet and outlet passages, an upper dial plate supported by posts on the base and a disk slidable on the posts and pressed downward by a coil spring between the plate and disk, upon three outer rods mounted in the base and a central cylinder. The outer rods are of copper and have a surface of polished gold so as to reflect as much of the light as possible, while the cylinder, which is also of copper, has its surface covered with lampblack, in order that it may absorb the maximum amount of light. This cylinder at the bottom rests on a valve controlling the gas inlet, and at its top it bears against a screw in the dial plate By manipulating this screw, the sensitiveness of the device can be adjusted to any desired degree. The spring shown inside the cylinder is for varying the coefficient of expansion of the cylinder. The whole device is inclosed in a glass cylinder to protect the parts from the weather.

The operation of the device is as follows: Changes in the temperature of the air will affect the rods and the cylinder alike, for they are of the same metal, but in daylight the polished surfaces of the rods will reflect the light and hence will absorb practically no heat. Meanwhile, the blackened surface of the cylinder will enable it to readily absorb heat which will cause it to lengthen and thus force the valve down on its seat and shut off the light. When darkness or fog comes on, the cylinder and rods again assume the same temperature, and as the cylinder again shortens, the pressure on the valve plate is relieved, permitting a small spring on the end of the plate to open the valve.

On the canal, the sunvalve will be used both with the constant flame lights and also with the flasher. Fig. 6 shows a light equipped with the flasher and sunvalve. In this arrangement the sunvalve will be interposed in the gas conduit between the governor and the flashing mechanism. As in the buoy lights, a pilot flame fed by a pipe direct from the governor must be employed.

For the whole canal and its entrances, about fifty light buoys and about ninety beacon towers, range lights, etc., will be installed, and this should be sufficient to insure safe navigation at all times.

How the Locks of the Panama Canal are Operated

(*Concluded from page 205*)

these devices in incorrect sequence; for instance, opening a gate when the chain fender is not in position or when the valves are open, etc.

There is also an interlocking combination that is used in connection with the intermediate gates which divide the locks into short sections. This arrangement is fitted with a Yale lock and key, so that the intermediate gates can be used only

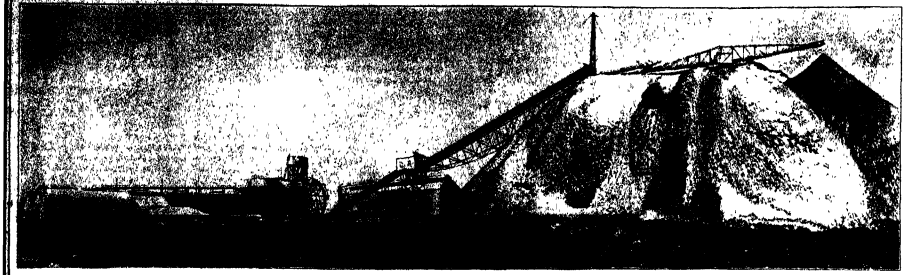
J. M. WILSON, Patent Attorney
37 Liberty Street NEW YORK CITY
[illegible]



KLEINFONTEIN MINE, JOHANNESBURG, SOUTH AFRICA

This gold mill is equipped with Rubber Conveying Belts aggregating one mile in length and in constant and satisfactory operation for 12 years. There are four sorting belts 36 inches in width on 100-foot centers, and 24-inch conveyors on which the crushers discharge 260 tons of 3-inch and smaller ore every hour. The total capacity of belts in the mill is 2000 tons a day. In addition, there are waste material belts 36 inches wide, conveying waste rock, ashes, cyanide and sand to the dump pile. These discharge from one to the other and run over steel trestles, mast and boom and cantilever structures, moving 2800 tons per ten hours. Other important installations of this type of conveying belt include the Lackawanna Steel Co, Buffalo; Edison Portland Cement Co., Stewartsville N. J., Crescent Sand & Gravel Co, Port Washington, L. I.; Solvay Process Co., Syracuse, Camden Coal & Coke Co., Philadelphia, Crane Valve Co., Bridgeport; Chase Rolling Mill Co., Waterbury, and hundreds of others.

Helping the Engineer Solve a Difficult Problem

The mining or mechanical engineer has many important problems to solve. Their accurate solutions are vital to his success.

Some of these problems are intricate and involved. In dealing with them the engineer finds that he saves time and labor, and doubly insures the accuracy of his results and the permanent utility of his work, if he calls to his aid specialists who have made a life study of some one branch or phase of engineering.

Connected with this company are members of the American Society of Mechanical Engineers and graduates of leading mechanical schools, who, in addition to their general technical training, have spent many years in the study of rubber from an engineering and scientific standpoint.

Their researches and experiments have not only resulted in the invention and improvement of various types of rubber belting, both transmission and conveying, but in the acquirement of a vast fund of specialized information which is invaluable to the mining and mechanical engineer.

This information is not a factory secret, except as to the formulae of our products. An important part of our work is educational. Members of our staff regularly prepare papers and lectures, illustrated and otherwise, for the benefit of technical schools, colleges, etc.

We are equally glad to give time and thought to the problems of the engineer. From the records of our large operations and our laboratory experiments, we can furnish many important facts and suggestions, and we are always pleased to be given the opportunity to do so.

Lamina Conveying Belt

This belt differs from other types of conveyor belt in a most important structural detail.

Its plies are laminated and independent

In a belt folded from one piece of fabric, each ply is affected by the wearing out of the first ply. Thus it often happens that when the surface wears out, the entire belt weakens and goes to pieces.

Not so with Lamina Belt. If the surface wears away and is entirely eliminated, the rest of the belt remains intact. The wear simply devolves upon the next ply, and so on, from ply to ply, abrading the belt by degrees, and thus greatly prolonging its life and usefulness.

It needs no extended argument to prove to the engineer that this type of construction is scientifically correct. It is sufficient to say that in hundreds of important installations, many of them of the most exacting nature, Lamina Conveying Belt has absolutely proved its superiority by giving a greater moving capacity and a longer endurance run, with less trouble and less repair than any other type of conveying belt in use.

Extensive conveying installations run heavily into money

In the end Lamina Belt will save a handsome percentage of that money. The proof is at your disposal

Have you undertaken the installation of a conveyor to move any kind of material, such as ore, coal, grain, phosphate, stone, cyanide, sand or cement?

If so, write us, stating the conditions and requirements fully. We can save you time and labor and help you to attain the highest degree of efficiency in the finished installation

---

Are you thoroughly informed as to the rapid strides recently made in the improvement of rubber belts and their proved superiority under all kinds of adverse conditions? Have you at hand exact, authoritative information as to the construction of rubber belts; the proper selection of duck; the correct principles of friction; the proper methods of handling and repairing; the correct manner of figuring requirements, dimensions, etc.? These, and other topics, are fully covered in a useful booklet entitled, "A Little Story of Rubber Belts." Send today for a copy of this book—it is free.

Condor BELT

Have you a mill to belt for power?

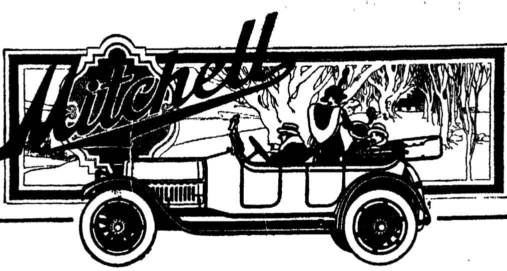
If so, you need Condor Belting It is the most expensive rubber belt made It is costly because of the labor and materials which are put into it, and economical because of the service it gives

Condor is the last word in heavy duty transmission belting In the quality and treatment of the rubber, in the selection and tests of the duck; in the scientific application of the friction, Condor stands in a class by itself

It is sold under the most sweeping guarantee ever placed behind a belt—a guarantee of more service or a new belt.

Condor is meeting with a constantly increasing and unprecedented success In mills of all kinds it sets new records in belt utility.

Let us know what your power belt problems are



Get the Personal Touch

If this particular advertisement can induce you to go to the nearest Mitchell dealer and take a ride in his demonstrator, then the object of the advertisement has been accomplished for we think the Personal Touch will sell the car

No sensible twentieth-century man will buy *anything* direct from an advertisement The real purpose of advertising is not to create a *demand* or make a *sale*, but to create *a desire to see* the article advertised.

The claims we make for this car are so many and they will sound so bombastic and egotistical in print that we haven't the heart to inflict them on you. The only way to prove the car is by *Demonstration* and the only way to make a demonstration is to get you in the car and *let you run it yourself.*

Sitting at the wheel of the *Mitchell you get the feel of the car.* You will understand after you have run the car a mile or so just what we mean by superb mechanism, ease of control, prompt response and knowledge of power You will understand without being told what we mean by sturdy build, engineering balance and proper distribution of strength and resistance to road strain. But no amount of advertising or printed matter can possibly make you understand or appreciate these features. You've got to *see* and *feel* to know

Running the Mitchell yourself you will get the *personal touch*—you will *know* just what the action is, whereas if you let someone else run it you will be accepting hearsay evidence. And we want you to know that it is a risky proceeding to invest a lot of money in an automobile on hearsay Any automobile looks good when it is running by you yet half of them will reveal coarse mechanism if you sit in the driver's seat and get the feel of the whole affair.

We welcome the personal demonstration. It leaves nothing whatever to chance It's the only way to buy an automobile and the only way to sell one If we were not absolutely sure of what the personal drive will do we would try the advertising and the hot-air plan of sale. But this car has performed so admirably for every man who has bought one that we know what it will do for you *So we don't fear the personal touch.*

Now then, if the personal demonstration pleases you—if the car performs to your satisfaction and you are sure of its action, don't buy until you ask yourself this most important question: "Will the maker of this car live up to the moral responsibility that every honest manufacturer should feel and observe? What is there behind him to prove that he will?"

The answer of the Mitchell makers is this: *"Eighty years of faithful service to the American Public*—eighty years of telling the truth—eighty years of building honest merchandise and selling it close to cost." And to confirm this we have the evidence of 30,000 Mitchell owners who love the car as we love it—who love it for what it has done and what it can do—who love it for its hourly, monthly and yearly efficiency, its lasting qualities and its economy of maintenance.

The families that created this concern eighty years ago, *own it yet.* The reputation they gained half a century ago for decency and honor remains intact today. This is your guarantee of insurance. This is the undeniable asset that goes with every Mitchell car and makes your purchase an investment rather than a speculation

No motor car is cheap. Nothing in the form of a vehicle that costs over a thousand dollars is cheap. Some cheap cars are awful cheap and some are mighty expensive whether cheap in price or not So that to get the full worth of your money and to be assured that you are not making a mistake, take the personal demonstration and ask who is behind the car that you are asked to buy.

Go to your nearest Mitchell dealer today and borrow his demonstrator for half an hour. Sit at the wheel yourself See how it feels to drive a car that has the real quality in it. If there isn't a Mitchell dealer in your neighborhood, write us direct at once and we will find a way to give you this *personal demonstration.*

Here is the Equipment for all the Mitchell Models Which is Included in the List Prices:

Electric self-starter and generator—electric lights—electric horn—electric magnetic exploring lamp—mohair top and dust cover—Tungsten valves—Jiffy quick-action side curtains—quick-action two-piece rain vision wind shield—demountable rims with one extra—speedometer—double extra tire carrier—Bair bow holders—license plate bracket—pump, jack and complete set of first class tools.

A model for every taste and requirement

Mitchell-Lewis Motor Co.
Racine, Wis. U.S.A.

Eighty years of faithful service to the American public

Unlimited Financial Stability. Ask Your Banker.

when the attendant [illegible] combination, this also being subject to the general interlocking system. Cross valves are used to cross fill between locks. These also are interlocked so that they can be operated only in proper order and combination to equalize the water between a pair of locks and save water which would otherwise be wasted. This cross filling consists in allowing water from one lock which is full to flow into a lock by its side in the other channel until the level of the water is the same in both locks, thus using a portion of the water over again.

The fact that the control board is a working miniature of the lock which it operates shows the operator the actual condition of gates, height of water, etc., and, consequently, having the whole condition in miniature under his eye he knows what to do next and when to do it; the operator receiving his information as to the movement of the vessel from a towing master.

How a Vessel is Locked Through.

Let us now take a vessel through a set of locks: It proceeds into the lock forebay either under its own power or that of a tug, and comes to a full stop. It then proceeds under the power and control of four electric locomotives—two forward to take it along, one on each side, and two others astern, one on each side, to keep the vessel in the middle of the waterway and to stop it when it has reached the proper point, and to prevent it from moving forward too rapidly.

After the vessel comes to a full stop in the forebay its position is given by the towing master to the switchboard attendant who, by moving a control switch lever, causes the lowering of the fender chain and the miniature fender chain on the control board after the lock gate is in the proper position.

Now the vessel advances into the lock by means of the electric locomotives. The fender chain is raised and then the massive gates are shut behind, the miniature control board gates in the meantime indicating this movement. When the water on opposite sides of the gates in front of the vessel has been raised or lowered, as the case may be, until the water on both sides is at the same level, as shown on the water level indicators on the control board, these gates are opened and the boat is pulled into the next compartment.

The Molecular Air Pump

(Concluded from page 208.)

second groove connects with the suction of a third groove whose pressure opening communicates with another suction opening and so on, the grooves being in series and the effect being cumulative. The pressure is lowest in the central groove and increases uniformly toward both ends of the cylinder up to the pressure produced by the rough pump. The last is connected by a rubber tube to the nozzle T which communicates with the interior of the casing B. The bearings of the shaft are oil-sealed, and the oil is prevented from penetrating into the casing by a spiral groove cut into the shaft which forces the oil outward against the atmospheric pressure whenever the shaft rotates. The spiral grooves act only when the shaft rotates with a certain speed, and it is therefore necessary in starting the pump to take care that the rough pump is not connected with the molecular pump until the latter has attained its full speed. On stopping the pump air must be admitted into it before stopping the driving motor. Fig. 5 shows the pump mounted on a common base with an electric motor of ½ horsepower which runs at 3,000 revolutions per minute. The pump is geared to the motor by a belt and runs at 8,000 to 12,000 revolutions per minute. The starting switch of the motor and the stopcock leading to the rough pump lock each other automatically so that a mistake in starting and stopping the pump cannot be made. As the new molecular pump acts directly by the motion of the molecules, it can be expected that it will remove not only the gases but also the vapors. This was shown to be the case in an [illegible] made to test the efficiency of [illegible]

[illegible] without the use of [illegible] anhydride or any other drying agent. The experiment consists in connecting to the pump a Roentgen tube of about 1 liter capacity. In about 10 seconds, starting with a pressure of 5 millimeters, the tube was evacuated to such a degree that sparks were formed in a gap of 15 centimeters connected in parallel with the tube. As a similar vacuum cannot be obtained in less than 100 seconds with the mercury pump, also designed by Dr. Gaede, it will be seen that the efficiency of the new pump is extraordinarily high. It has been found that whereas a pressure of 0.00001 millimeter of mercury is reached with Dr. Gaede's mercury pump in an average in 15 minutes, the same result is obtained with the molecular pump in 4 minutes, and this without the use of any drying agent.

Notes for Inventors

A Combination Condiment Holder.—Stanislaw I. Rocławski, of New York City, has secured a patent No. 1,070,535, for a condiment holder which includes two containers spaced slightly apart at their upper perforated ends with cut off means for controlling the discharge from their respective containers, the cut off means being connected for joint movement and having a part in the space between the container so that it can be operated by the finger of the user when the holder is grasped for use.

Life-Saving Appliance for Coal Mines.—Consul H. D. Van Sant of Dunfermline, Scotland, tells of an invention that is attracting attention among the coal miners of the Dunfermline district, being designed for the saving of lives in the event of a cage rope breaking in the mine pit. The invention includes two extra chains coming from the base of the rope and running down the side of the cage and fastening to four pieces of strong wood that project from the four bottom corners of the cage. When the weight of the cage is on these chains the wood pieces are drawn inside the framework of the cage, but when the weight is off, as when the rope breaks, the wood pieces project by means of springs and engage the bunting and bring the cage to a standstill.

Convict Ingenuity.—Convicts in close confinement and under what is regarded as very strict supervision, constantly surprise the public by the skill with which they avoid the authorities. We recall reading of a convict in the Tennessee State prison who was carrying on counterfeiting operations until the plaster-of-Paris molds were found, and it developed that he had succeeded in melting the baser metal by means of a wire connected up with the electric light wiring in his cell.

A Typewriter for Writing Bengali, an adaptation of an American machine already extensively used in India, is described in a recent consular report. The same typewriter had previously been adapted to writing seven Indian vernacular languages. The Bengali alphabet contains 360 characters, but many of these are identical with others in some of their parts. The actual number of characters engraved on the type blocks of the machine is only 92; these can be variously combined, with the aid of "dead," or non-carriage-operating keys and back-spacers, so that any letter in the alphabet can be produced. Apparently the adaptation cannot be applied to machines having a type guide, whereby the printing point is restricted within defined limits, or to shuttle or type-wheel machines.

Recording the Course of Enemy's Ship.—A patent, No. 1,084,907, has been issued to Francesco Spalazzi, a lieutenant in the Italian Royal Navy, for an apparatus for automatically and contemporaneously recording the course of the ship on which it is mounted, and of an enemy's ship. The apparatus during the travel of the ship on which it is mounted records automatically its course upon a drawing sheet or even directly on a sea chart and at the same time on the same sheet, and at the same scale it records the course of an enemy's ship, the [illegible] and position of which are thus [illegible] [illegible] and immediately

Legal Notes

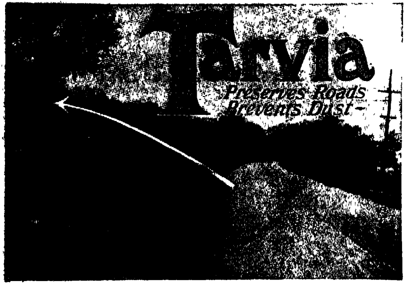
Delays in Prosecuting Patent Application.—In the case of *ex parte* Thomas wherein it was sought to revive an abandoned application, the Commissioner of Patents in granting the petition called attention to the fact that the response to the official action which the Examiner held was insufficient was filed in the Patent Office more than a month before the expiration of the year and said, "One who waits until about the last day to file a response does so at his own risk, but where the amendment is filed in ample time the applicant is entitled to some consideration."

What is Distinctive Name Writing?—In the case of Flanders & Flanders Manufacturing Company vs. Studebaker Corporation, Assistant Commissioner Frazier has held that the word "Flanders" written with a slight peculiarity in the letters with a paraph thereunder and with the upper end of the F extending in a long flourish thereover, is not written in such a distinctive and peculiar manner as to make the name registrable as a trade-mark, and quotes the decision *ex parte* C. H. Allen Company, saying "the distinctive manner in which the name is displayed must be of a character as to give such a distinctive impression to the eye of an ordinary observer as to outweigh the significance of a mere name."

Important Preliminary To Interference Declaration.—Following an order of the Commissioner of Patents, it is now proposed that preliminary to the declaration of an interference, the files of the interfering parties shall be submitted to the law clerk of the Patent Office for a final review, in order that his judgment may aid in determining whether the interference shall be declared. This is important, as it may avoid the declaration of interference in many cases where the interference should not be instituted, which cases frequently result in no benefit to either party and considerable expense to both.

Division of Re-issue Applications.—The new Commissioner of Patents, Mr. Ewing, early in his administration, indicated his intention of not blindly following precedents. In the case of *ex parte* Van Nostrand, he overruled a decision of many years standing, and held that where an application is filed for the re-issue of a patent, division cannot be required. In his decision, the Commissioner said, "the issuance of a re-issue patent is not the granting of a patent, but the exercise of the privilege of correcting a patent already granted, for which the law provides a fee different from the fee required originally, and I find no authority for requiring the applicant to pay more."

Some Adjudicated Patents.—The Colman patent No. 672,636 for a Knotting Machine has been held valid and infringed in Byrd Manufacturing Company vs. Colman; the Hall patent No. 692,277 for an Incubator as limited by the prior art and the specific language of the claim has been held not infringed in Hall, Mammoth Incubator Company vs. Teabout; the Smith patent No. 692,935 for weft-replenishing mechanism for looms, as to claims 13 and 14 has been held void for lack of patentable novelty in view of the prior Northrop patent No. 600,016, in Crompton & Knowles Loom Works vs. Stafford Co.; the Colman patent No. 755,110 for a knotting machine has been held valid and infringed in Byrd Manufacturing Company v. Colman; claims 2, 3 and 7 of the Keyes' patent No. 923,534 for an improvement in neckwear have been held void and claim 1 valid and infringed in Slip Scarf Company v. Blanchard & Price; claims 1 and 2 of the Miller patent No. 1,007,041 for a vehicle seat and lock have been held void for lack of patentable novelty and invention in Biddle v. Hodge & Graves Co. and the Coldwell & Gildard reissue patent No. 11,923 (original No. 637,234) for a warp stop motion for looms has been held void as to claim 19 as not for the same invention disclosed in the original patent and valid and infringed as to claims 23 and 25 in Coldwell-Gildard Co. v. Stafford



River Road, West Lafayette, Indiana. Constructed with "Tarvia X" Photographed two months after the flood

This road was 10 feet under water

The roadway illustrated above runs along the banks of the Wabash River at West Lafayette, Indiana.

In March, 1913, the great floods raised the river to the white mark on the tree at the left of the picture, completely submerging the macadam roadway.

This stretch of road was constructed in 1911 with "Tarvia X," and the condition of the highway after the flood gives ample demonstration of the fact that a Tarvia-bonded roadway is waterproof.

Tarviated macadam sheds an ordinary rainstorm immediately. Water does not percolate into the surface or loosen the Tarvia bond.

In this instance, the road got more than an ordinary wetting, but after the waters receded the macadam was found still in excellent condition, unchanged in contour, and ready for traffic without any attention or repairs.

"Tarvia X" is a dense, viscid, coal tar compound of great adhesive power and immune from damage by water or weather. Used as a binder, it so increases the strength of the macadam as to make it automobile-proof and erosion-proof. The saving in maintenance expense and the prolongation of the life of the road more than balance the cost of the Tarvia treatment.

Unity of interest means unity of effort

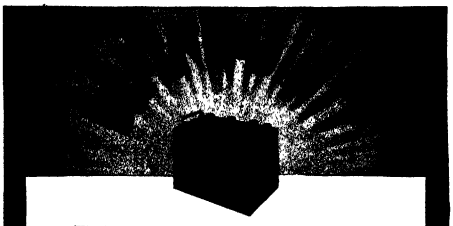
The owners, the board of directors and the executive officers of the Pierce-Arrow Motor Car Company are one and the same group of men. The

PIERCE-ARROW

organization is, and has always been, one of united individuality, one entirely free from outside interference by syndicates or any other form of external control

The Pierce-Arrow Motor Car Company builds nothing but motor cars, thinks nothing but motor cars, and all its surplus strength and energy are used to make its good motor cars better

The Pierce-Arrow Motor Car Co. of Buffalo, N. Y.



The heart, the mainstay, the vitality, the dynamic force —call it what you will—of every automobile electric self-starting and lighting device **is the storage battery.**

If that battery is not consistently powerful and unfailingly **dependable** all the skillful design and quality of the rest of the apparatus is very seriously handicapped.

The "Exide" Battery

For Auto Starting, Lighting and Ignition

has proved, under the most thorough and stringent tests, its ability to give automobile owners exactly the service they want and have a right to expect. Today throughout the country it is the one battery that is giving **real satisfaction.**

In two out of every three Electric self-starting and lighting devices the "**Exide**" is the battery that furnishes the motive power. Unfailing **dependability** under actual working conditions has demonstrated, beyond question, its superiority.

Realizing that the success of your self-starting and lighting device depends upon the quality of the battery with which it is equipped, are you going to be indifferent to the battery question or are you going to insist on the "**Exide**"—the battery that makes self-cranking and lighting devices absolutely **dependable?**

Think this over carefully. Write our nearest office for information.

The Flying Machine and Its Equipment

A Summary of the Air Navigator's Instruments

BEFORE it really came the flying machine was popularly conceived as a sort of winged bicycle running on air, a machine that could be taken out of the shed like a buggy. But when men actually flew they soon found that flying was far more difficult than was anticipated; that, indeed, it was peculiarly like sailing a ship far from land, because the ground appears very different from an altitude than from a horse and buggy, that the motion is so bewilderingly rapid to the novice that he knows not in what direction he is flying. He must determine his whereabouts in some way and steer a definite course. The direction in which the bow of the machine is pointed has little to do with the direction of actual motion; for the machine follows not only the thrust of the propeller and the rudder, but also the direction of the wind. Again, the wind, at a height may blow in a direction quite different from that indicated by weather vanes, the swaying branches of trees, clouds of dust, fluttering flags, and the smoke from chimneys. Speed and direction of flight can be determined only by experience. Soon the knack is acquired of ascertaining how much speed is due to the motor, how much to the wind.

To steer a definite course is difficult enough even in a motor-boat. It is still more difficult in an aeroplane, requiring as it does close attention and incessant vigilance to keep the machine from capsizing. Much of this work, unfortunately, is done instinctively. After some practice, balancing an aeroplane becomes as much a matter of course and requires as little thought as balancing a bicycle. He performs the necessary motions to keep it from falling absolutely unconsciously.

But a bicycle runs on a stationary support, while the aeroplane glides on an exceedingly unsteady body of air; that is one vital difference. Another is the fact that while the balancing of an aeroplane becomes partly instinctive, still the pilot does not immediately feel whether he is losing his balance, as he would feel if he were skating or running. Sometimes he must reason Why? Because he can control it only as long as it is speeding ahead. It is very easy to stop all progress of an aeroplane in spite of the motor and propeller simply by guiding it upward too suddenly. An aviator may easily do that, and no instrument will tell him of his danger. Indeed, if an aviator wants to ascend quickly, his instincts urges him to point the nose of his machine up sharply, whereas he should do so very gently if he really wishes to climb.

In making a curve the natural instinct is to bank strongly, to incline the body toward the center of the curve. But an aeroplane banks itself the moment it is turned because of its great span. One side in turning will always describe an essentially greater circle through the air than the other, and naturally moves faster. Therefore, it rises in the air. Hence, instead of helping the banking, the pilot has often to counteract the exaggerated rising tendency of one side. It takes experience to get just the right amount. If there is too much banking the machine does exactly what a bicycle does when banked too much in turning on a wet pavement In other words, it capsizes and falls toward the center of the turning circle.

Even when control is lost by steering upward there is a parallel in bicycling. After you have pedalled a bicycle up on a steep hill with great exertion, and follow a natural but wrong instinct to relax your efforts when you have reached the level course at the summit of the incline, you are surprised to find that the bicycle has lost all its speed. It almost stops, and you have to thrust out your legs to touch the ground and prevent it from falling. With a flying machine the ground is unfortunately far off, too far off to be reached by an outstretched leg. The aeroplane should really be compared with a bicycle running high on a wire, so that if it falls it falls into space.

$195.00 For This Wonderful 5-Room Portable Bungalow

This house has—
A hardwood floor, sand-smoothed, perfectly finished and double varnished. The under surface is creosoted to resist dampness, keep out vermin and preserve the wood—
Doors, awnings, transparent but unbreakable windows, a chimney and rustless screens for window and ventilator openings—
A frame of solid, clear, Mission-stained Washington Fir and rustless steel—
All parts fit together with "Hook-on" and "Slip-in" joints. Instructions furnished are so plain that two persons can completely set up the house to live in the day it is received.

Kenyon

There is nothing like the Kenyon Take-Down House—there cannot be anything like it because all of its important features are covered by patents. Let this modern, portable bungalow form the basis of your plans for the summer—
A complete summer residence shipped so conveniently packed that it can be easily conveyed on an ordinary wagon and the price, $195.00; other sizes, from one to seven rooms, $55.00 and up.

In view of all these difficulties, successful cross-country flying is made possible only by instruments which curiously resemble those employed in navigating ships on the perilous ocean. It is obvious that a single flyer cannot make the best possible use of them. He has his hands too full. When it is remembered that a whole staff of navigation officers watch the nautical instruments aboard a ship, we realize how much is expected of the aviator. The navigating problems of the air so greatly exceed those of the water in difficulty that only dirigibles which can carry a whole staff of navigating officers are equal to the task. It becomes evident what an overwhelming advantage the two and three-seated aeroplanes have over the one-seated aeroplane.

The first instrument needed, an instrument never absent in an aeroplane, not even in the school machines that fly only above aviation fields, is a revolution counter for the motor. This is the same as that used on automobiles, and consists of a flexible shaft connected with the motor, a casing containing clockwork and a dial on which a hand travels over figures. Thus the number of revolutions made per minute is indicated. The aeroplanist cannot know how strong is the wind at the level at which he is flying; but the revolution counter sufficiently indicates what speed the machine itself is making to allow him to estimate the proper direction to head his machine.

The same service is performed, but more efficiently by another instrument with which many machines are now equipped, namely, a wind gage that measures directly the actual speed of the machine in the wind. This instrument renders another most valuable service: it shows the pilot when he is losing speed, and with the speed, the control of the machine. Formerly pilots used to depend for this information on the feeling of the wind as it struck their faces.

Similar benefits are derived from two incilnometers—levels that tell the pilot just how much he has inclined his machine fore and aft or from side to side It has been found that even a trained eye may be deceived about the actual position assumed; that in darkness the pilot loses all judgment, although he may be occasionally guided right in the dark by blind instinct. Unfortunately a fluid level, an air bubble or a pendulum device is subject to many disturbances aboard an aeroplane because of the inertia and momentum of the moving masses. Pilots will eagerly adopt a trustworthy gyroscopic indicator that will fulfill the difficult task of indicating the true horizonal Once such an instrument is invented flying will become fifty per cent safer, and will be possible even in the dark.

The control of the motor itself requires many instruments. If the aviator is alone, it may indicate only when trouble is coming, and when he should prepare himself for a downward glide, assuming that the faulty motor has not yet lost him his speed and control. If he is not alone his companion should be able to remedy the irregularities indicated by the instruments. As yet designers have given much attention to mounting the motor within easy reach of one of the passengers.

There is not the inevitable steam gage—because the engine is a gasoline motor—but a dial on which the proper circulation of the cooling water is indicated. Another dial shows the working of the lubrication system. There is a switch for throwing in or cutting out the electric ignition. Some machines have also an electric meter showing the strength of the electric current that makes the spark, and guaranteeing, therefore, that the spark is efficient. And there is a pressure gage in every machine that indicates the amount of air pressure in the gasoline tank by which the fuel is forced to the motor.

Most important is, of course, a float or a glass fluid level that shows how much gasoline is in the fuel tanks; without it the motors might suddenly cease to work over a locality where even by a long glide from a great elevation, the pilot could not reach a safe landing place.

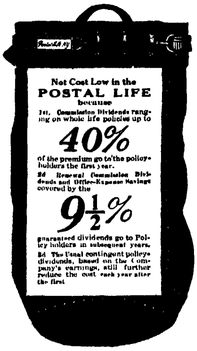
High flyers have discovered why birds are so warmly covered with down and

Send for *Official Information* and *Satisfy* Yourself About the Postal Life Insurance Company

Insurance-protection is not for a day or a year, but for a lifetime, and the best to buy is the **legal-reserve kind,** such as is issued by the standard old-line companies.

The Postal Life is one of these: they are all subject to the same **strict supervision,** and their policyholders are protected by the same **legal and governmental safeguards.**

The Postal differs from others chiefly because it **does not employ agents**; it does business **direct** and gives its policyholders the **benefit of the commissions that other companies pay their agents.**



Net Cost Low in the POSTAL LIFE because

1st. Commission Dividends ranging on whole life policies up to 40% of the premium go to the policyholders the first year.

2d. Renewal Commission Dividends and Office-Expense Savings covered by the 9½% guaranteed dividends go to Policy holders in subsequent years.

3d. The Usual contingent policy-dividends, based on the Company's earnings, still further reduce the cost each year after the first.

If you want to find out fully about the Postal Life, **don't take the word of an agent of some other company**; he is naturally prejudiced, and besides that, he is bent on influencing you his way so as to get a commission

And don't depend on what such an agent may show you in some insurance periodical which he carries about in his pocket: the article was printed for the special benefit of agents and **not for your benefit.**

Write to the Company itself for **official information,** including its Financial Statement for 1914, with a facsimile **Certificate of Valuation of the Insurance Department of the State of New York.**

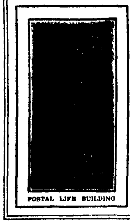
Furthermore, as the Postal Life does not establish itself in the various States, it is **not subject to taxes, licenses, and other State exactions,** which means further economy All these savings appear in **generous dividends to policyholders.**

The Company may also be able to refer you to policyholders in your immediate vicinity. It considers **satisfied policyholders its very best asset.**

ASSETS AND LIABILITIES

At the close of business, December 31st, 1913, the Company had nearly $50,000,000 of insurance in force: its policy and other liabilities were fully covered by statutory and departmental reserves amounting to $9,543,218.25, with an excess of surplus to policy holders of $230,043.93.

The Company's reserves and other assets are in approved securities, including State, municipal and railroad bonds and mortgages, real estate, policy-loans, accrued interest, deferred net premiums, cash in bank and various other items, aggregating $9,848,159.



POSTAL LIFE BUILDING

Simply write to the Postal Life and you will receive, as stated, **official information** based on reports regularly filed with the New York State Insurance Department under whose strict supervision the Company does business

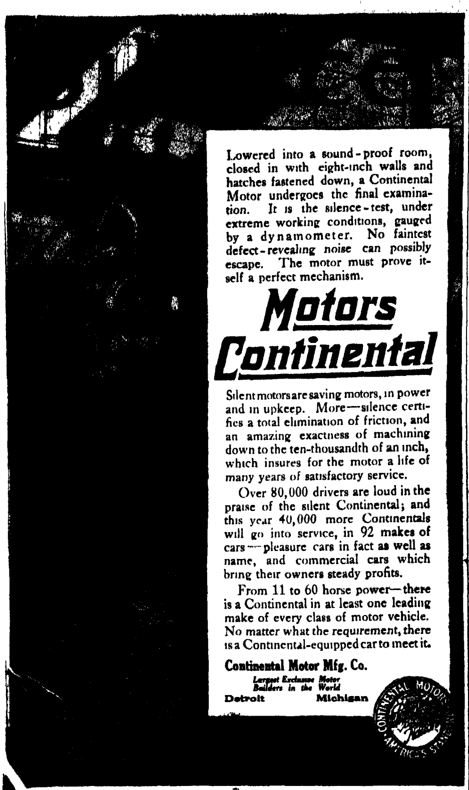
GOODELL-PRATT COMPANY

Toolsmiths

Greenfield Mass. U. S. A



Lowered into a sound-proof room, closed in with eight-inch walls and hatches fastened down, a Continental Motor undergoes the final examination. It is the silence-test, under extreme working conditions, gauged by a dynamometer. No faintest defect-revealing noise can possibly escape. The motor must prove itself a perfect mechanism.

Motors Continental

Silent motors are saving motors, in power and in upkeep. More—silence certifies a total elimination of friction, and an amazing exactness of machining down to the ten-thousandth of an inch, which insures for the motor a life of many years of satisfactory service.

Over 80,000 drivers are loud in the praise of the silent Continental; and this year 40,000 more Continentals will go into service, in 92 makes of cars—pleasure cars in fact as well as name, and commercial cars which bring their owners steady profits.

From 11 to 60 horse power—there is a Continental in at least one leading make of every class of motor vehicle. No matter what the requirement, there is a Continental-equipped car to meet it.

feathers. Flying is a cold sport—as cold if not colder than ice-boating. The stinging blast of the upper air becomes unbearable to a pilot of an aeroplane. Remember he is traveling at a speed of sixty to eighty miles an hour. The warmest clothing has been tried. Still, the cold eats its way through. Pilots reach the ground numb, and apathetic, which perhaps explains some accidents that have happened at the end of long, high flights.

There is no reason why a few tubes connected with the motors should not convey the hot water from the cylinders around the pilot's cockpit. That is possible in European machines; for the barbaric method of seating the pilot in empty air at the edge of the lower plane of biplanes still compulsory in the American Wright and Curtiss machines, has been discarded abroad in favor of well protected cockpits. A heated cockpit could be provided with a windtight cloth cover that buttons to the aviator's dress like an Eskimo's "dojak."

In Austria, Etrich has seated the sorely tried pilots in a completely inclosed limousine of good stream line form, made of mica. Thus, even noxious head resistance is saved; for at sixty to eighty miles an hour, any part of an aviator's body that is exposed to the wind, wastes power.

Some foreign aviators have installed in their machine a little desk on which to write notes and make little sketches. Some French machines in the last Paris show were even equipped with a little locker for food and with heating devices. Such conveniences are particularly reasonable in machines designed for two pilots with double controls so that one man may refresh himself not only with rest, but also with food and drink while the other takes his turn in guiding the machine.

A serviceable device in aeroplanes is the pilot's belt. Aviators like the oarsmen in Venetian galleys must literally be strapped to their seats. At times the wind forces the machine around with a violence that finds no parallel even in a small sailing ship in the heart of a tempest. Caught by the air the machine is hurled down so suddenly (without capsizing or getting out of control) that the inertia of the pilot's body would cause him to fly out of his seat and lose his grip on his levers unless he were held down. In fact, pilots have been pitched out of machines that were still under control and killed. It was then that the French invented the aviator's strap, a strap that holds the body fast and is still a bit elastic, a strip wide, very strong, and capable of being instantly released in case of a smash of the machine.

Flying has developed other safety devices. A life-belt against drowning does not necessarily inspire one with awe because it may be useful in learning to swim. But it is different with a safety helmet that performs its function only after you have fallen head foremost. These helmets consist of fixed padding filled with resilient, coiled, steel wire. They may save a man from a cracked skull, but not from a broken neck.

If not crowned by a helmet, aviators' costumes are usually topped by a sort of skull cap to cleave the wind with the least trouble. A weird barbaric feature of this cap or helmet is to be found in the little roll or screen at the side of the head, right in front of the ears to protect the eardrums somewhat against the terrific clatter of the motor's open exhaust. A muffler would not consume very much power. It has been tried successfully in England, and is, in fact, furnished, if desired, with the newest models of Wright biplanes. To protect the eyes from the icy blast and from flying oil, goggles are worn.

All these instruments and implements deal with the mere function of flying, of keeping afloat in space. To navigate the aeroplane, an embryonic edition of a mariner's navigating instrument is required. The compass is indispensable. Numerous difficulties, connected with its use aboard aeroplanes, have been gradually overcome. The first is the excessive vibration of a frail and small craft—an engine room as it were—with a motor

Do You Remember Bernhardt's Debut?

To many of us the Divine Sarah has long been a pleasant memory.

But that memory consists mostly of farewell tours—it doesn't go back to her initial performance.

It seems impossible that she ever made a first bow, and waited expectantly for the verdict of an audience.

But she did!

At Booth's Theatre, N. Y., in 1880, she gave her first American performance.

And though it seems so long ago—Richmond Straight Cuts were then already established as the best of all Virginia cigarettes.

During all the years since Richmond Straight Cuts made their first bow and received the acclaim of particular smokers, they have maintained the same high standard of quality. Today—as then—they are the best of all Virginia Cigarettes.

Liggett & Myers Tobacco Co.

equipment of nearly one fifth the power of that of a mammoth dirigible. Aeroplane compasses are now floated in a liquid contained in a vessel that is supported on a bed of resilient felt-chips. A formidable obstacle to the use of the compass is the mass of iron in the powerful motors, necessarily in close proximity to the magnetic needle. It is no easy task on shipboard to arrange pieces of iron around the compass so that no matter how the ship may turn, and in what position the mass of its hull may be relatively to the needle, the needle will always turn to the north. An aeroplane turns not only around a vertical axis, but also around a horizontal axis when it is inclining. It turns, moreover, more suddenly than a ship. Still the aeroplane compass has been made fairly reliable.

For cross-country flying a map is as necessary as a compass. Maps for aviators are different from other maps. They must not contain too much confusing detail. For quick reading they must emphasize those features which most resemble the general outline and the principal landmarks visible on the ground. They must chart the dangers to the aerial navigator—eminences, such as church towers, factory chimneys, even high trees. All suitable landing places must appear on the map, as well as telegraph wires and high-tension conductors. Very important is the indication of the different levels of the ground. Without that a machine may easily come to grief.

Moisant employed an easy method to hold a definite course with map and compass. He simply picked out some prominent landmark, the tower of a church, for instance, in the general direction of his course, fixed his intended direction on the compass dial and noted the changing position relatively to his chosen mark. When he came too near to the latter he picked out a new one. In the recent flight from Berlin to Vienna an officer guided an aviator, whose passenger and helper he was, even above the clouds, simply by taking his direction from the sun and computing the sun's position by his watch. This presupposes an extraordinary sense of locality. Using the same principle, a compass has been constructed for aviators that is simply a sun dial reversed. As a sun dial will give the time when the points of the compass are known, this instrument, of identical construction, will give the points of the compass if the time is indicated by a perfect chronometer. Astronomical tables showing the changes of the sun's position with the seasons must be consulted. Even finding a place astronomically by taking the sun's height is now taught to German aviator officers, thanks to Prof. Marcuse, who has designed instruments with which these measures may be taken very easily and quickly, by means of an artificial horizon and tables with hardly any figuring. Such methods will be of great benefit to an aeroplane that has completely lost its way above clouds.

It is often of the greatest importance that the aviator should know his altitude above sea level. So, after nautical localizing, he should be able to read his altitude above the ground from his map, which should give ground altitude in order to be absolutely accurate. Thus the aviator is able to keep clear of the ground and its many dangers.

It is always well for the aviator to know his exact altitude. Therefore, he carries a barometer—not the old-fashioned kind with mercury in a long glass tube, but a little contrivance that indicates by clockwork on a dial the deformation of an elastic casing from which the air has been exhausted. Aeroplanes also occasionally carry barographs—the same sort of barometer, but one that automatically registers the changes of altitude during flight on a sheet of paper.

The Wireless Telegraph Station at Punta Arenas, on the Straits of Magellan, is expected to be in full operation early this year. It will be a station of 100 kilowatts, comprising seven tubular steel masts 200 feet high, and costing over $150,000. A provisional installation on two of the masts has already established

Good Shoes—Good Paint

Every building at the plant where Packard Shoes are made is painted with "High Standard" Paint

Three years ago the large plant of the M. A. Packard Co., of Brockton, Mass., was painted with "High Standard" Liquid Paint. They are so well pleased with the way the paint is wearing that they are using it on a new addition.

If you want real protection for your buildings—if you buy on the basis of quality or service, not first cost alone—"High Standard" Paint will be your choice.

Lowe Brothers High Standard LIQUID·PAINT

is the most beautiful, enduring and economical of paint. We can prove this to you by tests made throughout a third of a century.

Lowe Brothers "High Standard" Liquid Paint is scientifically made—as carefully compounded as a physician's prescription. No guesswork. After a long service it leaves a good surface for repainting.

Valuable paint book free

"Paint and Painting" is full of pointers that every one ought to know in purchasing paint. It's interesting, too. Send for a copy today.

When You Buy a Typewriter Let Its Record Guide the Purchase

ALL KINDS OF WRITING MACHINES ARE MANUFACTURED, BUT THE

UNDERWOOD

IS THE

Recognized Standard of Merit

This is NO IDLE STATEMENT. It is an AXIOM

The oldest scientific body in the United States, the Franklin Institute of Philadelphia, put the Underwood through tests for a year and then awarded it the Elliott Cresson medal.

Here is the wording of the award:

"In recognition of the very meritorious inventions embodied in the Underwood Standard Typewriter, and of its exceedingly simple and efficient details of construction, forming a writing machine of the most advanced type, with unsurpassed capabilities and excellent make-up throughout, the Institute awards the Elliott Cresson Gold Medal to the Underwood Typewriter Company, for the ingenuity, skill and perfection of workmanship displayed in the Underwood Typewriter."

IN ADDITION TO THIS THE

UNDERWOOD

HOLDS ALL INTERNATIONAL RECORDS FOR
SPEED, ACCURACY and STABILITY

"The Machine You Will Eventually Buy"

communication with the station in the Falkland Islands and with vessels passing through Magellan Straits. A secondary station will be installed at the Evangelistas Lighthouse, at the Pacific entrance to the straits. Navigation through the straits will be greatly facilitated by the new stations.

Recent Advances in the Art of Lacquering

By L. V. Redman, Department of Industrial Chemistry, University of Kansas

THE art of lacquering metal consists in placing a thin transparent film of varnish upon the polished surfaces of metals such as silver, brass, copper or German silver, to serve as a protective coating and prevent the rapid tarnishing of these surfaces by such agents as oxygen, sulphur, acid vapors, and the active reagents in the air, e. g., coal smoke and furnace fumes. Lacquers have consisted generally of natural gums dissolved in suitable solvents to which have been added small amounts of drying, vegetable, oils; these oils serving as agents to toughen and temper the brittleness of the resins and allowing the lacquers to be applied easily and smoothly. The solvents are alcohol, amyl acetate (banana oil) wood spirits, denatured alcohol, ethyl acetate, wood distillates, nitro-benzene, benzol, petroleum spirits and turpentine. The resins, gums or waxes are kauri, gum elemi, soft copals, shellac, ceresin, casein. These resins are very largely replaced by artificial materials such as nitro-cellulose, cellulose acetates, celluloid and cellulose formate

The oils added to decrease the brittleness consist of linseed, tung oil, and castor oil. Other materials used for this purpose are camphor and glycerine. Recently, that is, within the last four years, there have appeared on the market lacquers of new order These lacquers are composed entirely of synthetic resins dissolved in the regular lacquer solvents. They contain no oils, no natural resins or gums, and in fact have no natural product of any kind whatsoever in them. The raw materials for these varnishes are very wonderful and the synthetic lacquers stand as a monument to the modern chemist's skill. They consist of carbolic acid, which is obtained from the tar that collects upon the sides of the ovens when coal is being roasted to produce illuminating gas or coke, and formaldehyde, which is produced from wood alcohol by incomplete combustion.

When carbolic acid (or phenol, the general name applied by chemists) and commercial formaldehyde, in equal volumes, are heated together for some time, there results an amber-like resin which, if not heated too long a time or at too elevated a temperature, is soluble in alcohol, amyl acetate, nitro-benzene, aniline, wood distillates, carbolic acid and many other solvents The reaction between the carbolic acid and formaldehyde may be hastened very much by the introduction into the mixture of such foreign substances as salt, washing soda, acids, alkalies, and salts generally. These foreign substances are added in small amounts and are used for the sole purpose of hastening the reaction. As their rôle is not well understood in the reaction, the chemist is satisfied to say that they act catalytically and the substances are called catalysts, meaning that the reaction is hastened by their presence, although they do not enter directly into the reaction. As the formaldehyde is volatile, the reaction is carried on in closed vessels fitted with reflux condensers, to prevent the escape of the gaseous formaldehyde After the heating has continued for the desired length of time, generally one hour, the mass is allowed to cool and the gum is taken from the vessel, washed well in water to remove the catalyzer and then dried. The result is a resin not unlike common resin in appearance and possessing many of its physical properties. The resin melts at 80 deg. to 100 deg. Cent. It is rather brittle, dissolves readily in the common solvents, except petroleum products, and when about 20 per cent by weight is dis-

[illegible]

solved in 70 per cent alcohol and 10 per cent amyl acetate, it makes a lacquer which dries very rapidly to a hard lustrous coat.

The article thus coated and dried is subjected to a process of heating for different periods of time, from a few minutes to several hours, depending upon the temperature and the thickness of the coat. The temperature ranges from 125 deg. to 200 deg. Cent. The higher the temperature the more rapid is the transformation. This heating process imparts the most wonderful properties to the lacquer. After the heating it is completely insoluble in all ordinary solvents, and the lacquer may be allowed to stand in alcohol or acetone for weeks at a time without suffering the slightest depreciation. Acids and ammonia have no effect whatsoever upon it, and strong alkalies dissolve it only very slowly.

The lacquer may be applied either with an ordinary brush or air brush, or the article may be dipped in the lacquer. After coating by any of these methods the article is dry in the course of an hour and may be placed in the oven for heating. The baking is generally complete after one hour, and the article is removed from the oven and is ready for the market. Two or more coats may be given to the article if desired before the heating process is begun. Generally two coats are sufficient. Articles thus lacquered are of special value in chemical and medical laboratories to withstand the corrosive fumes of the chemicals. Microscopes, polariscopes, and instruments which are made largely of brass, copper or silver, retain their luster indefinitely when thus coated. The lacquer also has much more extensive uses in the lacquering of brass beds and brass and copper household ware, such as candle-sticks, trays, candelabra, brass urns and all kinds of beaten copper and brass.

Once the article is properly coated with this lacquer its surface is immune to the attack of solvents and the atmosphere. It may be immersed in alcohol, acetone, dilute acids, alkalies, or washed with hot soap and water, without injury. Ammonia, vinegar, or other solvents likely to be found in the average home has no effect upon it. The lacquer may be injured by the use of such cleansers as contain grit in any form, as the grit actually cuts off the lacquer by erosion. In every other respect the lacquer is permanent. It possesses a durable lustrous surface, is quite transparent and elastic in thin films, and possesses a light golden color which may be made any desired color by the use of the proper dyes or pigments

Philippine Government Students in the United States

FOR a number of years the Philippine government has been sending young Filipino men and women to the United States to receive a collegiate education with a view to appointment to higher positions in the government service. Up to date 211 of these "pensionados," as they are called, have been sent over, and a large number of these have been appointed to office on graduation. Hereafter a different policy is to be followed, as the islands now have a university of their own, where natives may receive thorough training in all undergraduate subjects. Accordingly, pensionados will only be designated for postgraduate study in the United States. The Philippine legislature, at its last session, provided fifteen fellowships for advanced work at American institutions.

Explorers Using Wireless Telegraphy

THE Italian expedition to the western Himalaya and the Karakorum, under Dr. F. de Filippi, is equipped for wireless telegraphy and is preparing to use this means of determining longitude in its surveys. The outfit has been tested in India, where it was used for time signals between Simla, Delhi and Lahore, and subsequently between Skardu, in Baltistan, and Lahore.

Wood Distillation

For Manufacturing ALCOHOL and other Products of the Process

¶ Profits from refuse wood and sawdust are in reach of any one who will locate near a sawmill. The Scientific American Supplement files contain a series of valuable articles on this topic which are contained in the following numbers:

No. 1610—A General Review of the Subject of utilizing wood wastes, and the uses to which the wastes may be put.

No. 16[illegible]—The "steam" and "destructive" distillation process, and names the numerous products obtainable from the complete operation.

No. 1661—Distillation of soft wood, and gives the proportions and quantities of each product distillable, and the various processes used.

Nos. 1723 and 1724—The general subject of the utilization of wood wastes, giving all the products by a clear and valuable diagram showing their relations to each other, and many illustrations of apparatus.

No. 1[illegible]—The manufacture of wood alcohol by a German process which first converts sawdust and shavings to glucose and then to alcohol, leaving the residue of the wood with 75 per cent of its heating value, and in condition to briquette without a binder.

No. 178[illegible]—Prof. [illegible]'s article on the manufacture of wood alcohol, a very comprehensive discussion.

No. 1643—Dry distillation of Beech and other hardwoods comparing European and American methods, and giving the quantities of products obtained.

No. 1335—Charcoal manufacture in Germany, with complete recovery of by-products, their description and uses.

No. 1472—"Distillation of Pine Products" refers especially to turpentine manufacture, but covers the by-products as well, and gives information of the profitable nature of the business.

No. 1161—Refers to acetic acid, wood spirit and acetone from distillation of wood, and gives a good description of the necessary apparatus, and particularly of the precautions to be observed in operating the plant.

No. 1736—Production of Alcohol from Cellulose, how wood and wood products may be used.

No. 1[illegible]—Turpentine from waste wood.

No. 1910—The production of ethyl alcohol from waste products (sawdust, etc.)

No. 19[illegible]—Experiments in the hydrolysis of [illegible], sugar and alcohol from wood.

No. 19[illegible]—[illegible]

No. [illegible]

EACH number of the Supplement costs 10 cents. A set of papers containing all the articles above mentioned will be mailed for $1.70. Order from your newsdealer or from us.

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are *sharp*, the articles *short*, and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

Mawson and Wilkes

IN March, 1839, when the ancient belief in the existence of a great *terra australis* surrounding the south pole had been generally abandoned, an English sealer, John Balleny, had the first distant glimpse of the long coast-line south of Australia now known as Wilkes Land. Balleny did not, however, realize the significance of his discovery, and for aught he or the world knew to the contrary he had merely sighted some islands of no greater extent and importance than those which he had previously discovered farther to the east, and which now bear his name.

Early the following year two expeditions, neither of which knew anything of Balleny's discovery, sailed closer to the coast in question and sighted land at several points. One of these, under Dumont d'Urville, discovered Adélie Land and Clarie Land, but did not suspect them to be parts of a continental mainland. The other expedition, under Lieut. Charles Wilkes of the United States Navy, traced the coastline for so great a distance that the leader had no hesitation in naming it "the Antarctic Continent." If Wilkes and his companions had not been sent upon their Antarctic quest in ill-provisioned and half-rotten ships, unsuited in every way for exploring in high latitudes, it is altogether probable that the American expedition would have effected a landing somewhere along the coast, and brought back the definite and detailed information in regard to this region for which, as fate would have it, we have had to wait over seventy years.

During the rest of Wilkes's lifetime and long afterward his discoveries formed a bone of contention among geographers. As lately as 1885 Sir Clements Markham wrote in the ninth edition of the "Encyclopædia Britannica" (art. "Polar Regions"): "In 1839 the French expedition under Dumont d'Urville proceeded south from Tasmania and discovered two small islands on the Antarctic Circle named 'Terre Adélie' and 'Côte Clarie.' At the same time Commander Wilkes of the United States expedition made a cruise to the southward and mapped a large tract of land in the latitude of the Antarctic Circle for which he claimed the discovery. But as a portion of it had already been seen by Balleny, and the rest has since been proved not to exist, the claim has not been admitted."

Even in England, where skepticism regarding the American discoveries has been perpetuated as a heritage from the unfriendly counterclaims of Sir James Ross, few geographers have taken so extreme an attitude on the subject as is indicated in the above paragraph. "Wilkes Land" has appeared intermittently on British charts from at least as far back as 1850, the year in which was published the second edition of A. Keith Johnston's "Physical Atlas," which shows this land as an unbroken coast-line extending for about 1,500 miles in approximately its true position. In recent years the controversy has narrowed down to a question concerning the existence of Wilkes's last reported landfall to the west. Where the American commander thought he saw "appearances of land" to the southwest, and marked Termination Land on his chart, neither the "Challenger" nor the "Gauss" expeditions were able to find land, and the Mawson expedition has now definitely proved its non-existence. Whether Wilkes mistook ice for land, or actually saw the distant coast lifted into visibility by refraction, or—a much less probable supposition—made an error of over a hundred miles in his position, will probably remain a mystery.

On the other hand, the Mawson expedition, which has just completed its labors in the Antarctic, has removed the last vestige of doubt concerning the reality of the continental coast discovered by the American expedition three quarters of a century ago.

The Supreme Court's Pure Food Decision

WHILE the decision of the Supreme Court in the bleached flour case will probably prove a bitter disappointment to many, it was a decision that must have been expected by those who have closely followed the wrangles to which the pure food law has given rise. The Referee Board has shown beyond the shadow of a doubt (and the experiments conducted by *ex-parte* investigators in Europe and America confirm its findings) that very small quantities of injurious substances have no harmful effect.

As we understand it, the decision by no means goes so far as to hold that food which is unfit for human consumption may be treated with harmless proportions of injurious chemicals in order to make it marketable. It does however throw upon the Bureau of Chemistry the task of proving conclusively that a questionable food is so noxious that its sale should be forbidden.

In these days of the high cost of living a food manufacturer of honest intentions should not be too greatly hampered in his effort to place a wholesome product upon the market at a reasonable price. To be sure, the question of wholesomeness may give rise to a hot controversy; but it is for the very settlement of these questions that the Bureau of Chemistry and the Referee Board exist.

That the Bureau is now doing its work competently and adequately we are convinced. The bleached flour case must be regarded as a heritage from a time when the physiological findings of the Bureau were not all that could be desired, and the decision is not to be considered as a reflection upon the present personnel of the Bureau. No doubt the decision will have the effect of increasing the Bureau's work. More analysts will probably have to be engaged, and more stations for the examination of food products established. Congress has been exceedingly generous in its appropriations for the Bureau's work, and there is no reason to suppose that it will be any less liberal in the future than it has been in the past. Surely the task of guarding a whole nation's health is so important that Congress will not spare any expense in attacking it properly.

How to Help the Poor Inventor

WHAT good are laws if inventors are poor? Put money into the patentee's pocket and at once the difficulties of inventing are cleared away—so we would gather from a bill introduced by the Hon. Mr. Samuel W. Smith in the House of Representatives and ordered to be printed.

First of all a workshop is to be created "where all records, books, models, drawings, specifications, and other papers and things pertaining to inventions designed by inventors *without* means shall be safely kept and preserved." Next a commission, to be elected "by direct vote of the people," is to set the price or royalty to be paid the inventor for his invention. By *direct vote of the people*, mind you! Visions of primaries, conventions, caucuses arise. The selection of the commission assumes the importance of a presidential election. All the elaborate political mechanism of the electoral system is to be set in motion.

But the commission presumably has nothing to do with inventors who have money. Only "inventors without means" are considered. The man who can scrape together the statutory Patent Office fees is probably not "without means." Therefore the existing patent laws apply to him. Not for him is the Inventors' Workshop in which his ideas are to be worked out, not for him is that "farm of suitable size and locality," provided for by Mr. Smith, in order to try out "machines adapted for use in cultivation of the soil, and gathering its products." That unfortunate is just rich enough to escape good luck, as it were.

There are some compensations for this lack of poverty. "All inventions worked out at said Inventors' Workshop shall be the property of the United States Government." Instead of falling into the maw of some greedy trust, the poor inventor is to be devoured by his own Government, he is to be propped up with one arm and knocked over with the other.

In a section which contains only two lines, the Hon. Samuel W. Smith disposes with classic brevity of the intricate subject of infringements. "The Government shall pay for all patents and defend all law suits for infringements." The Book of Genesis is not more simply worded. Representative Oldfield of Arkansas, whose compulsory license theories have been made a target by manufacturers, must feel that he is a blind reactionary with medieval ideas when he considers this simple and highly progressive method of dealing with infringement suits with a mere wave of the hand.

The people are not forgotten in Mr. Smith's scheme. "The Government shall establish factories where inventions shall be manufactured and sold direct to the people at cost." Government ownership encroaches on a new field. Nor are the factory workers overlooked. No slave driver, no miserable sweatshop, shall profit by the poor inventors' labors. The workers are "to receive for their labor the full equivalent of their production in maximum uniform wages."

Even the interests of mankind are considered. "No invention or inventions intended to be used in the prosecution of war or destruction of human life, or for the composition of any drugs, foods, or articles injurious to human health and happiness" will be considered at all.

Dreamers, too, are discouraged. Take heed, you Marconis with absurd wireless apparatus, you Edisons with silly phonographs, you Bells with imbecile schemes for telephoning! If your inventions possess no *commercial value* at the time they are conceived, if the world must be educated to use your machines you may not enjoy the privilege of having the Government work out your inventions for you. Go to the trusts, to Wall Street capitalists with your dreams. This is a practical Congress, a practical Government.

During the seventy years of the SCIENTIFIC AMERICAN's existence we have commented on more than one well-meant patent bill introduced in Congress by some representative of the people whose heart bled when he contemplated the plight into which inventors seem to fall. We have even advanced a few ideas on the improvement of the patent system ourselves—but hesitatingly and with some fear that the Constitution of the United States might in some way curb our philanthropic enthusiasm. But all those who have hitherto tried to better the lot of the inventor—ourselves included, we shame-facedly admit—must yield to the Hon. Samuel W. Smith in breadth of vision and largeness of heart. Compared with the epic magnificence of the project which is unfolded in his measure, far too modestly entitled "A Bill to establish an Inventors' Workshop," all other plans seem mean and niggardly.

A Place Where Wireless is Needed

THE island of Tristan da Cunha, in the middle of the South Atlantic Ocean, has from time to time been a source of worry to the British Colonial Office. Communication with this tiny colony of less than one hundred people is very infrequent and irregular, and as the resources of the island are limited, the inhabitants occasionally stand in need of outside assistance. In 1885 nearly all the able-bodied men of the island were drowned while attempting to board a vessel, and the survivors were for a time dependent for existence upon a supply of stores and provisions sent to them by a British man-of-war. Several unsuccessful attempts have been made to induce the people to abandon the island and settle elsewhere. At the present time the Crown Agents for the Colonies are inviting tenders for a license conferring the exclusive rights to occupy three neighboring islands—Nightingale, Inaccessible and Gough—for whaling, sealing and guano gathering, with the provision that whenever the licensees dispatch a vessel to or from the islands it shall touch at Tristan da Cunha for mails and goods, and that they shall also maintain good order in all the islands of the group. An admirable philanthropy would be the establishment of a wireless telegraph station in this isolated spot, after the good example recently set by an English newspaper in putting the little island of St. Kilda into wireless communication with the mainland of Scotland. Of course, such an undertaking in Tristan da Cunha would be far more costly both initially and for maintenance, owing to the great distance of the island from any existing wireless station.

The Aurora Borealis

SOME very interesting recent researches by Størmer and Birkeland on the Aurora Borealis render it probable that this phenomenon is due to corpuscular radiation proceeding from the sun to the earth. These corpuscles are doubtless electrons which are known to have great penetrative power. It is interesting to notice that these observations furnish a means to evaluate the actual degree to which the space in the solar system is a vacuum. It may be expressed by saying that it is as much rarer than the most rarefied vacuum yet produced experimentally as this latter is rarer than the ordinary atmosphere. The density of this interstellar vacuum varies within the limits of the solar system with its distance from the sun; and is doubtless very much more feeble in interstellar spaces far removed from any stars. Outside the Milky Way we may have a vacuum which is almost absolute. The subject has been fully discussed by Birkeland himself in the SCIENTIFIC AMERICAN SUPPLEMENT.

Dr. H. E. Hamberg retired from the directorship of the national meteorological service of Sweden on January 6th, and was succeeded by Dr. Nils Ekholm.

Electricity

Dissipating Fog by Wireless.—The North Railroad Company in France is making experiments on the use of wireless waves for clearing away fog. It is well known that electric waves act upon the water particles which make up fog, so as to dissolve them and turn them into vapor. Following this idea, it is claimed that as much as 600 feet can be cleared up in front of the electric wires which are sending out the waves, the fog being at least partially dissipated, and this will have a great value in practice, especially for railroads and vessels at sea. The latter will have time to avoid each other in this case.

Wireless Telephony from Berlin to Vienna.—Wireless telephony continues to occupy experimenters in various parts of Europe, and although we have no very remarkable progress to report within a recent date, we wish to mention some promising experiments which are being carried out between Germany and Austria. The Nauen wireless station, owing to its high mast, is favorable for long-distance working, and telephoning was done from this plant to the Technical Museum at Vienna, which makes the distance to be 300 miles or more. Owing to special apparatus of a new design, it was possible to hear newspaper articles which were read at Nauen.

Cleveland Electrical Exposition.—Cleveland is planning a great electrical exposition to be held May 20th to 30th in the Coliseum. The project is to be given under the auspices of the Electrical League of Cleveland. The Sixth City claims to lead the nation in many departments of the electrical trade. It is the headquarters for the greatest lamp works, the home of the biggest carbon manufacturing plant, and it boasts of three leading manufacturers of electric vehicles. It holds highest rank in the manufacture of electric cranes and hoisting machinery, and is a leader in the making of batteries. It claims many of the largest electrical machinery plants and its public service company is said to be a model of progress and efficiency.

Memorial to Wireless Operators.—As a memorial to wireless telegraph operators who have lost their lives at sea, it is planned to erect a fountain in Battery Park. The fountain will be of white granite with seats of the same material at either side. At the back will be a column upon which the names of the operators will be inscribed, as follows: Jack Phillips, S.S. "Titanic," April 15th, 1912, Atlantic Ocean. George C. Eccles, S.S. "Ohio," August 26th, 1909, Pacific Ocean. Stephen F. Sczepanek, S.S. "Pere Marquette," September 9th, 1910, Lake Michigan. S. Lawrence Prudhunt, S.S. "Rosecrans," January 7th, 1913, Pacific Ocean. Donald Campbell Perkins, S.S. "State of California," August 18th, 1913, Pacific Ocean. Ferdinand J. Kuehn, S.S. "Monroe," January 30th, 1914, Atlantic Ocean.

The New Army Automobile for X-ray Use, which is constructed on designs of the French army physician Major Busquet, is very complete and represents the most recent progress in this direction. In field work of the kind, it has been found difficult to operate the X-ray apparatus with good success owing to the various manipulations which must be carried out, and again a suitable photographic dark room has to be provided. Another point is that quite an amount of power is needed to operate the electric devices if any satisfactory results are to be had. A roomy automobile with 12 horse-power motor and a dynamo has now been developed, the inside of the car being fitted as a laboratory and dark room. A folding operating table is provided with the X-ray bulbs and all needed fittings, and a tent set up against the side of the car forms an operating room. The tent is then folded and stowed in the car. In time of war, it is claimed that all difficulties of operating will thus be overcome, and the car will also be of good service at all times, and can reach the spot quickly. Aviation centers can thus have good aid, especially where a large hospital is not to be found in the locality.

Increasing Motor Output.—A somewhat original method is used by the Brown-Boveri works to increase the amount of power which a given electric motor can be called upon to furnish; for instance, where a factory is using a motor rated at 500 horse-power, the new method allows of getting considerably more out of it, say 700 or 800 horse-power. This often makes it unnecessary to put in new motors for the increase of a plant, hence a great saving. The method depends upon the fact that in the induction motor the power factor often has a low value, so that the motor does not furnish nearly as much power for its size as it would were the power factor of higher value or near to unity. For rolling mill motors, where these are subject to severe strains and overloads at times, the motor must be very much larger than the average power would call for, hence it is an advantage to be able to use a smaller motor for the same power. This is done by a small extra device in the shape of a one horse-power motor, coupled to a rotating commutator, and this acts to change the value of the power factor and increase the output of say a large 1,000 horse-power motor with which it is used. The small device is connected to the circuit of the large motor.

Science

A Unique Collection of Books has just been acquired by the Library of Congress from Mr. Bertram Dobell of London. It consists entirely of works printed for private circulation, 1,500 in number, covering a wide range of subjects, and representing a labor of forty years on the part of the collector. Mr. Dobell has prepared an interesting descriptive catalogue to accompany the collection.

Mink Breeding.—A contribution to the growing industry of fur farming has been undertaken by the U. S. Biological Survey in the shape of experiments in breeding minks for size, quality of fur and disposition. A mink farm has been started near Prichard, Idaho, in the Coeur d'Alene National Forest, and similar experiments are under way in the National Zoological Park in Washington, D. C.

Earthquake Construction has now reached a very practical stage in the seismic districts of Italy, where all new buildings are being erected under strict supervision with respect to their ability to resist earthquake shocks. Prof. Omori, the Japanese authority, has estimated that 99.8 per cent of the deaths in the great Messina earthquake of 1908 would have been prevented if the buildings had been properly constructed.

The "Discovery," which was built for Capt. Scott's first expedition and was frozen in the Antarctic ice for three years, was subsequently sold to the Hudson Bay Company, and Scott was unable to obtain her for his second journey to the Antarctic. Mr. G. F. Stackhouse has, however, been more fortunate, having secured the use of this stanch vessel for his expedition, which is to seek King Edward VII. Land next Summer.

Martian Frosts.—The following telegram has been received from Lowell Observatory: "A late frost, a unique phenomenon, occurred on the night of March 3rd on Mars, in the region to the north of the Propontis, and was still visible at 2 o'clock of the Martian afternoon. The frost was parted from the north polar snow by the blue border, which was undoubtedly water, that marked the melting cap."

Suttee, the ancient Hindu custom of burning widows on their husbands' funeral pyres, was made illegal by the government of India in 1829, but cases of its occurrence are still occasionally reported. The London *Times* describes the voluntary suttee of a young widow last June at Yaraule, a village in the Mainpuri district. The act was carried out in the presence of a crowd of from 1,500 to 2,000 people. Several natives who assisted at the ceremony have been sent to prison.

The Death of Prof. Robert K. Duncan.—Dr. Robert Kennedy Duncan, Director of the Mellon Institute of Industrial Research of the University of Pittsburgh, died recently after an illness of several weeks at his home in Pittsburgh. He contributed articles on scientific topics to many periodicals, including the SCIENTIFIC AMERICAN. In 1907 he inaugurated at the University of Kansas a plan of industrial fellowships which subsequently has been developed to large proportions in that institution and at the University of Pittsburgh.

News from the "Polar Bear" Expedition.—A dispatch from the Signal Corps station at Circle City, Alaska, dated November 11th, announces the arrival at that place of a courier who brought a message 250 miles overland from the Arctic coast stating that the power-schooner, "Polar Bear," with a party of explorers and big-game hunters on board, is frozen in the ice off Demarcation Point, where it will, necessarily, spend the winter. All the party were reported well. A quite unusual number of vessels are understood to be fast in the ice along the Arctic coast of Alaska this season, including part of Stefánsson's Canadian Arctic expedition.

Casein.—Recent notable developments in the production and industrial uses of casein form the subject of an interesting report from Consul W. H. Hunt, stationed at St. Étienne, France. Casein, which is the principal albuminoid matter of milk, is now obtained by electrolysis, according to the following recently invented process: In the middle of a large vat full of skimmed milk heated to a temperature of 80 deg. C., a porous vessel is placed containing a 5 per cent solution of caustic soda; an iron cathode is plunged into the soda, and a rod of carbon, serving as an anode, into the milk. An electric current sets free the phosphoric acid contained in the milk, and the casein precipitates. As compared with the method of obtaining casein by the use of acids or rennet, the cost of this process is very low, the yield is greater, and the casein produced contains no foreign ingredients. Vegetable casein, now produced on an extensive scale from the soya bean, can be put to the same uses as animal casein. The principal use of casein is in the manufacture of galalith (milk stone), used as a substitute for ivory, tortoise shell, celluloid, etc. Penholders, frames, purses, phonograph disks, and a great variety of other articles are now made of galalith. It is also used as a chemical fertilizer. Several other casein products have recently been introduced.

Aeronautics

The "Loop" and its "Loopers."—Up to the present time no less than thirty-one pilots have looped the loop, according to *L'Aerophile*. Of these, Hamel, an Englishman, and Gilbert, a Frenchman, have looped the loop with passengers.

A New Tri-plane.—Eugene Bouillet of Long Island City, N. Y., has secured patent No. 1,084,248 for a triplane which has an upper supporting surface with the rearwardly projecting lateral tips, an intermediate supporting surface with controlling surfaces in its lateral extremities and a rectangular lower supporting surface, the said surfaces having substantial flat forward and rearward portions and a transversely extending arched central portion.

German Aeroplane Motor Competition.—Another aeroplane motor competition is to be held in Germany. The sum of $35,000 is to be awarded for the best water-cooled and air-cooled motors of 80 to 200 horse-power. The tests will determine general working of the motors, the efficiency, consumption of fuel, etc., and endurance. Among the points that will be counted in favor of a competing engine, the possibility of using cheap and safe material of German origin will be included. Points to be avoided are: Long duration of preparations for the tests, special requirements as regards lubricating oil, decline of efficiency in the long distance trials, vibration, breakdown of carbureters, an inconvenient shape for fitting into the aeroplane, and the supply of materials from abroad.

A Flying Tug-boat.—M. Maurice Colliex, who has been trying to solve the question of hydro-aeroplanes of large dimensions, capable of flying out over the sea for an entire day, made his first flight, recently, with a new gigantic sea plane, which might be called a flying tug-boat, built by the Voisin brothers. It has the regular ship-like under-structure characteristic of Curtiss hydro-aeroplanes, and looks something like a small river tug. Even the funnel in the middle is not missing. The hull of the little boat is 26 feet long, with a beam of 7 feet. The wings, which form a sort of tandem biplane, two super-imposed planes being at the back and two in front, are about 82 feet long, and have a spread of about 150 square yards of canvas. There are two motors of 200 horse-power each, and the machine is capable of flying with a useful weight of about two tons. It can carry oil and fuel enough for a flight of about 100 miles. Colliex tested the machine on the Seine, near Triel. It rose easily from the water, and alighted without difficulty.

Fog Observations for Aeronauts have been made regularly in Germany since March 1st, 1913, under the auspices of the *Luft-Fahrzeug-Gesellschaft*, at a small group of stations surrounding the town of Bitterfeld, where the service has its headquarters. Dr. Rotzoll, who is in charge of this novel undertaking, points out in his first report on the operations of the service that a foggy atmosphere is one of the greatest dangers encountered by airships, and it is therefore of the utmost importance to keep the aeronaut informed of the location of fog, its density, the height to which it extends, etc. Experienced meteorological observers are now keeping a record of fog at places around Bitterfeld, and are prepared to send reports by telegraph or telephone whenever called upon to do so. They report the density of fog in terms of "visibility-distance", i. e., the maximum distance at which certain prominent objects, such as steeples, smokestacks, etc., can be seen. In order to measure the height of fog, apparatus is now being constructed which will be sent aloft attached to a captive balloon or kite; when the instrument rises out of the fog into drier air the change in hygrometric conditions will be registered electrically at the other end of the wire leading to the ground.

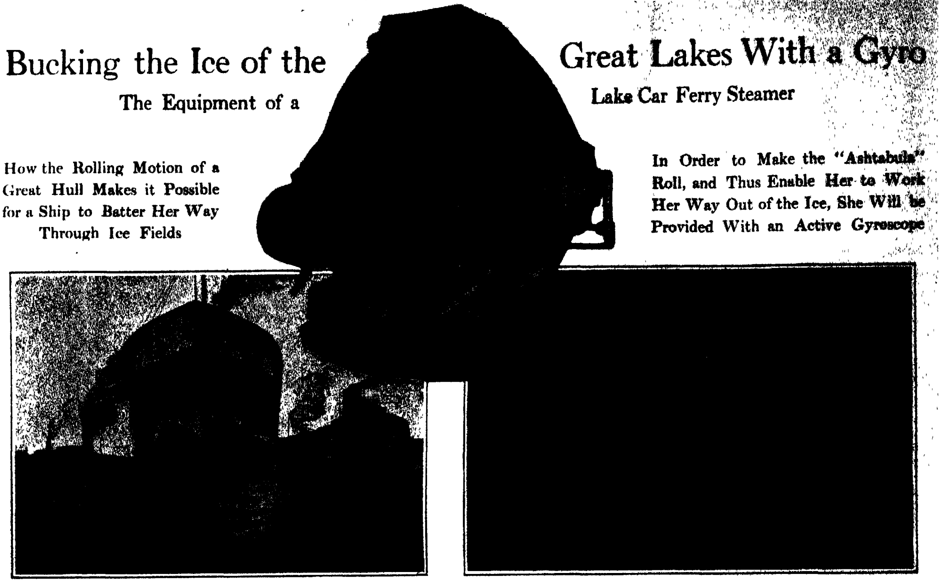
The Italian Air Fleet.—The Italian airship M-3 is finished and is now beginning her trials, while the P-3 has terminated those with success, and is said to be destined for Turin. These two additions to the Italian airship fleet bring its numbers up to ten, consisting of five of the P—piccolo = small—class, three of the M—medium—category, the "Citta di Milano," built by Ing Forlanini, and the "Parseval." We are informed by the *Engineer* that the first example of a new semi-rigid series, distinguished by the letter V after the designer, Capt. Verduzio, is under construction near Rome, and will have a capacity of 15,000 cubic meters (529,721 cubic feet) and a speed of 90 kilometers (56 miles). In Milan, another Forlanini vessel will soon be begun, with a capacity of 15,000 cubic meters, and therefore larger than the "Citta di Milano," besides having greater speed. The plans are also said to be well ahead for the new G—grande = large—type, which will be rigid and have a capacity of over 30,000 cubic meters (1,059,442 cubic feet). In the aeroplane department, three squadrons of seven machines will be added by June to the sixteen already existing. By the end of the year, there will probably be in Italy seventeen military aviation squadrons, each of seven aeroplanes, together with thirteen airships, of which the newest and largest will be the new Forlanini ship, the V-type unit, and the large G.

Bucking the Ice of the Great Lakes With a Gyro

The Equipment of a Lake Car Ferry Steamer

How the Rolling Motion of a Great Hull Makes it Possible for a Ship to Batter Her Way Through Ice Fields

In Order to Make the "Ashtabula" Roll, and Thus Enable Her to Work Her Way Out of the Ice, She Will be Provided With an Active Gyroscope



A big steamer on the Great Lakes having a channel broken for her by small tugs with special rudders.

The manner in which the stabilizing and rocking gyro will be installed on the "Ashtabula." G is the incased gyro; P is the precessing engine.

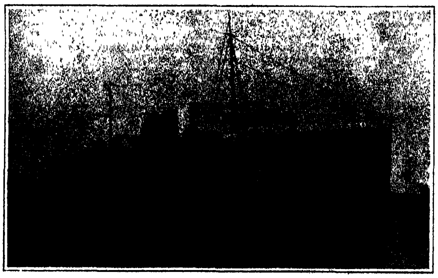
The gyroscope is shown in the top picture. C is the vacuum case containing the active type of gyro; E is the electric motor which drives the gyro.

MANY millions of tons of freight are hauled annually by vessels upon the Great Lakes, and many more millions could thus be carried were it not for ice. On an average, general navigation upon these highways of inland shipping is limited to a period varying from seven to eight months—depending upon the severity of the winter season.

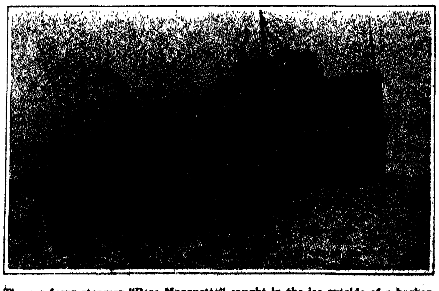
It is not necessary that the Great Lakes, from shore to shore, should be frozen over to halt the activities of freighters; it is quite enough to have harbors closed by the ice. In order to reduce the impediment of this lesser evil, it is customary to employ small vessels to break passages clear for inbound or outbound craft when the rest of the lake area is open to navigation. Strange though it may seem, these modest craft do what their big brothers, *the freighters, cannot do even though many* efforts have been made to fashion some of the lake steamers so that they can "buck the ice" effectively. Despite the fact that the Russian ice-breaker "Ermak" has done excellent work, that ship has its limitations. It is not always possible to get sufficient headway to ride up on the ice and break it down, as the "Ermak" does, and, besides that, she is fit for that service alone and powerfully—we might almost say extravagantly—engined for that work.

The ice-breaking tugs on the Great Lakes are equipped with exceptionally large rudders which can be swung quickly from side to side by a steam-steering engine and thus given a rhythmic rocking motion, tuned to their natural rolling period, by which it is possible for them to deliver first on one side and then on the other crushing blows to the ice while being driven vigorously forward by their screws. The result is a capacity to break the ice in a manner which the straight, bow-on attack of far heavier vessels would not accomplish even though it be possible for them to poke their stems up and on the floe.

The big car ferry steamer "Ashtabula," a vessel of 4,500 tons, is to be equipped with a unique apparatus by which that ship can be rocked like the small tugboats when attacking the ice. In this way, the rolling motion of her great body will make it possible for her to batter her way through the ice fields and to get in and out of harbor unassisted. The "Ashtabula" will be fitted with a Sperry stabilizer of the active gyro type, which when not in service to steady the craft in a seaway, can be made to roll her agreeably to her natural period. The Sperry installation will take up but a modest amount of space and will weigh less than one per cent of the ship's total displacement. When stabilizing the "Ashtabula" the mechanism will receive its inciting impulses from the waves themselves. When rocking the ship, the promoting action will be arbitrarily induced by a small auxiliary apparatus which will affect the two little pilot or sentinel gyros which bring the great gyros into action either to one or the other side.



The car ferry steamer "Ashtabula," which plies between Ashtabula Harbor, Ohio, and Port Burwell, Ontario.



The car ferry steamer "Pere Marquette" caught in the ice outside of a harbor.

Briefly, the active force employed is centered in a large rapidly revolving flywheel in which the principal mass lies in the rim, and the faster this gyro turns the greater its upsetting or corrective *energy when swung laterally to varying* degrees out of its normal fore-and-aft vertical plane of revolution. Thus, within a moderately small compass, an immense measure of disturbing or counter-balancing energy can be aroused. It takes but a relatively small amount of power on the part of a precession engine to turn the gyro to right or left as far as need be. Of course, when on duty, the big gyro is steadily spinning. The precession engine is called to service by two little gyros: one regulating the time of action and the other the degree of movement. These extremely sensitive sentinel gyros operate, by means of electrical connections, the throttle of the engine control and the manner of applying the steam to what we might call an ahead or a backing motion—in this case resulting in movements on the part of the gyro to right or left.

The object of the auxiliary apparatus referred to will be to artificially excite the pilot gyros by a purposely applied rocking motion. This, in turn, will be translated to the big gyro, and its periodic precession will cause the 4,500-ton ship to rock in unison. This opens up an entirely new field in the problem of breaking through ice that interferes with traffic, and the working of the installation in this case will be watched with intense interest by ship owners as well as engineers.

The 31,000-ton "Pennsylvania" of the United States Navy. She will carry twelve 14-inch guns.

The Problem of Our Navy

III.—The Decline of the United States Navy to Third-Class Rank

By the Editor

BETTER than any learned treatise could have done, the events of the Spanish war taught the American people the value of a preponderance of sea power. When Dewey crumpled up the Spanish fleet at Manila and Sampson strewed the southern coast of Cuba with the burning wreckage of Cervera's squadron, the decisive influence of sea power, always recognized by the naval expert, became self-evident, even to the man in the street.

The effect of this object lesson upon the country at large and its representatives in Congress was immediate. Proud of its navy and the international prestige which followed upon its victories, and realizing that what the navy had won a strong navy alone could keep, Congress lent a willing ear to its technical advisers, and systematically and most liberally set itself to the task of building up a navy that should be equal to the heavy responsibilities entailed upon the country by its acquisition of such widely separated possessions as Porto Rico and the Philippine Islands, and by its occupation of the island of Cuba. Our navy grew, literally by leaps and bounds, and within half a dozen years of the conclusion of peace it stood second in strength, with a commanding lead over that of Germany, having as its first fighting line not less than twenty-three first-class battleships built or under construction, to say nothing of eleven armored cruisers—the latter a type which Japan, not many months before, had not hesitated to place in the first line at the great battle of Tsushima.

But it so happened that in the very year, 1905, which found our navy in such a commanding position, there was built in England a new type of battleship, the "Dreadnought," which was destined to work a revolution in the relative standing of the navies of the world, by relegating all existing battleships to the second line.

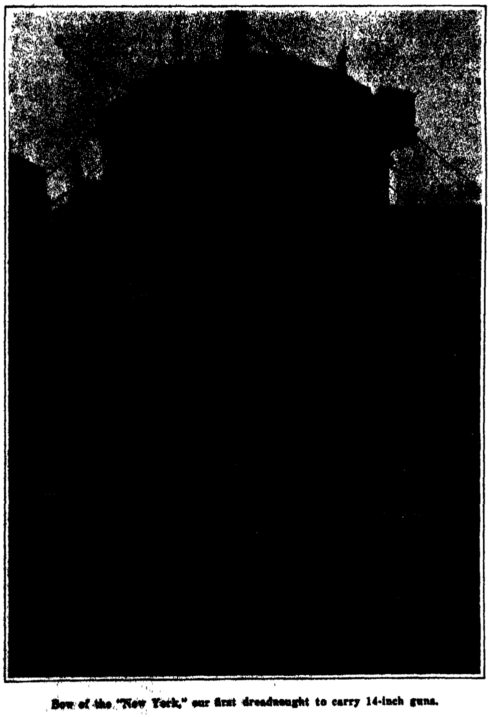
So vastly superior in size, speed, gun power and defensive qualities was the new ship, that it was recognized as the only type that could be used effectively in the first line of battle; and it was realised that the nation which could most quickly build and equip a fleet of these ships would hold the balance of sea power with all that this implies. The leading powers recognized that the dreadnought had entirely upset existing conditions, and all but ourselves accepted the burden thus laid upon them, enlarged their naval appropriations accordingly, and made haste to build up a new battleship fleet along dreadnought lines.

Unfortunately, Congress failed to appreciate the serious nature of the crisis; and at the very time when appropriations should have been increased to meet the new conditions, they were reduced—with the result that our first line of battle (and that means the navy, so far as the winning of decisive engagements is concerned) has sunk to the third rank, with France and Japan pushing us very closely for pre-eminence. But the story of the rise and decline of our navy since the war with Spain is told by the statistical figures of the following table.

APPROPRIATIONS FOR ARMORED SHIPS SINCE THE SPANISH WAR.

Date.	Battleships	Armored Cruisers
1898	Three	
1899	Four	Two
1900	Two	Three
1902	Two	Three
1903	Five	
1904	One	Two
1905	Two	
1906	One	
1907	One	
1908	Two	
1909	Two	
1910	Two	
1911	Two	
1912	One	
1913	One	

An analysis of the above table shows that in the seven years, including and intervening between the Spanish war and the opening of the dreadnought era, Congress authorized the construction of new battleships at the average rate of two and one half ships per year, and of battleships and armored cruisers combined at the rate of four ships per year; whereas during the eight years covering the dreadnought era, when a far-seeing Government would have accelerated construction, we have authorized new battleships at the low average rate of only one and one half vessels per year. And let it never be forgotten that during these years of decline in relative strength, our international policies have grown in scope and have been proclaimed with greater emphasis than ever before.



Bow of the "New York," our first dreadnought to carry 14-inch guns.

Why is the Dreadnought Supreme?

Now we can well understand that to many of the people of the interior States, and to many of their representatives in Congress, for that matter, the sudden announcement that their fine navy, for the upbuilding of which Congress had appropriated money so freely, has in a few years dropped to third-class rank, will come with a shock of surprise and provoke a strong doubt as to its truth. That doubt has been freely expressed, and by no one so strongly as by those senators and representatives whose constituencies are to be found in the interior States, where, in the nature of things, knowledge of naval affairs is not so broad, and familiarity with the development of naval *materiel* is not so intimate, as in the maritime States.

The present false conceptions of our naval standing, the failure to realize the imperative necessity for maintaining our navy in the very front rank among those of our possible competitors, and the indifference of the people and Congress to the fact that, ever since the dreadnought era began, we have been falling rapidly to the rear—all this is due to lack of information, to much positive misinformation, and more than anything else, perhaps, to a belief that no foreign power will dare to attack us—a belief which is founded partly upon our past naval successes and partly upon our feeling of national invincibility, that is to say, upon what remains of a certain traditional "lick-creation" attitude toward the great outside world.

But the day has gone by, never to return, when the ability of a nation to win a great naval war can be measured in terms of its material wealth and its undisciplined courage. *The modern development of the technical arts, to which this country has contributed so greatly, has put a heavy discount upon mere wealth and courage, and has set a heavy premium upon the material instruments of war—the 14-inch gun, the telescopic sight, the torpedo, the destroyer and the submarine!*

But the "man behind the gun"? Yes, we have a good man behind the gun; but so has Germany, so has Japan. The 14-inch, rifled gun, sending its high-explosive shell unerringly to the mark across five miles of water, is no respecter of persons. The stalwart American gun-pointer at one end of that five miles and the puny Jap at the other are toeing the line in a scratch race, a race which will be won, not by brawn and muscle, not by unconquerable courage, not by any dreams of a glorious past, but by the steady nerve, the keen eye, and the poise that comes of unremitting training and discipline in the years gone by.

Now let us carry the line of thought a little further and remember that what is true of a single gun is true of a whole ship's battery, and that, if gun is equal to gun, and the marksmanship is the same, by all the laws of probability, the ship that carries the greatest number of guns and delivers the heaviest broadside will win the fight

To-day, even more than when Napoleon uttered his famous dictum, it is certain that "Heaven fights on the side of the heaviest artillery;" and it is because the dreadnought carries a broadside of such overwhelming superiority that no pre-dreadnought can engage it with the slightest hope of success. A 12-gun "Wyoming" might silence a 4-gun "Connecticut" in the first five minutes of an engagement, and in 10 minutes might conceivably leave it in a sinking condition But, according to Representative Witherspoon and the "small navy" men in Congress, matters would be equaled if twelve 4-gun "Connecticuts" were pitted against four 12-gun "Wyomings;" and since herein lies one of the most plausible fallacies of those who fail to see the importance of the dreadnought question, we shall now give, *seriatim*, the reasons that have relegated all but twelve of our thirty-nine battleships to the second line.

I. *Overwhelming concentration of gun-fire.* It is generally agreed that because of the danger of fighting in the head-on position (which exposes a ship to the risk of a raking fire in which more shells would strike and when they struck might pass through the whole length of the vessel), that future engagements will be fought broadside to broadside, with the two fleets traveling on parallel courses, and the ships disposed in "column formation," that is to say, ship behind ship, with a suitable interval of about 450 yards between the stern of one ship and the bow of the ship that is next astern. In this formation a line of four "Wyomings" would be roughly about one mile in length, and a line of twelve "Connecticuts" nearly four miles. The "Wyomings," because of their superiority in speed of about three knots, would elect to place themselves opposite the head of the column of "Connecticuts," and in these relative positions, the four "Wyomings" would be able to oppose forty-eight 12-inch guns against the sixteen 12-inch guns of the four leading ships of the "Connecticut" line. The "Wyomings," having the advantage in speed, would elect to fight at a maximum range of 10,000 to 12,000 yards, and since the successive ships down the "Connecticut" line would be at increasing distances from the "Wyomings," the after part of their line would be out of effective range. The result would be that the four "Wyomings" would be able to crush the head of the "Connecticut" line by overwhelming gun fire, and then commence dropping back until the whole fleet had been silenced The "Wyomings" would be punished, of course; but their enormous volume of fire would fairly smother that of the ships at the head of the enemy's line and would afford a strong protection against his gun fire.

But suppose that the twelve "Connecticuts" found themselves in line against twelve "Wyomings," with forty-eight 12-inch guns opposed to one hundred and forty-four!

II. *The all-big-gun battery makes salvo firing accurate.* The fact that only one caliber of gun is carried in the dreadnought's main battery gives it an enormous advantage over the pre-dreadnought. The "Connecticut" carries 12-inch, 8-inch and 7-inch guns. If all of these are engaged, it is impossible to distinguish the splash of the several guns, and the work of the spotter is rendered difficult and uncertain. With the guns all of one size, the spotter can determine the mean point of fall and correct the elevation of the whole ship's battery accordingly. Because of the terrific punishing power of the 12-, 13½-, and 14-inch gun, the commander-in-chief will prefer to fight his dreadnoughts at the maximum range at which he can hit the mark and trust to the accuracy of his fire to land on the enemy that first salvo which will go far to win the fight. At such ranges, only the four 12-inch guns of a "Connecticut," "Georgia," or "Maine" would be available—and even these, being of an older type, would be greatly outclassed by the more modern guns of the dreadnought. The 8-inch, 7-inch and 6-inch guns would not even be manned during the fight

III. *The more modern equipment* of the dreadnought's guns would enable them to do more accurate and faster firing.

IV. *The armor of the dreadnought* is thicker, of better quality, and is better distributed.

V. *The saving in personnel on the dreadnought* is a most valuable feature. The "Connecticut" carries 1,000 officers and men for four big guns, the "Pennsylvania" carries the same number for twelve big guns—250 men per gun for the pre-dreadnought and only 84 per gun for the dreadnought.

VI. *Lastly, the relative damage of a hit by torpedo or gun*, tending to sink the ship, is one half as great on the 31,000-ton "Pennsylvania" as it is on the 16,000-ton "Connecticut." Furthermore, the compartmental subdivision of the dreadnought as a protection against mine and torpedo is more elaborate and effective than on the pre-dreadnought type.

The forward 14-inch guns of the United States dreadnought "New York."

We have said enough to show that the dreadnought, as a fighting unit, is in a class by itself. To send a fleet of pre-dreadnoughts out to fight a fleet of dreadnoughts would be suicidal. The case was aptly put by Mr. Daniels, the Secretary of the Navy, in his examination before the House Naval Committee, when he said that the captain who fought a pre-dreadnought against a dreadnought would be deserving of court-martial.

On the new dreadnought rating, then, where do we stand? Naval statistics show that there is one first-class navy, the British, with forty-two of this type built and building; one second-class navy, the German, with twenty-six such ships; and three navies of the third class, that of the United States with 12; France with 11 and Japan with 10 dreadnoughts. And both France and Japan, be it remembered, are building faster than we. They are adding to their dreadnought fleets at a rate which in a few years' time will relegate us to the fifth position.

Unless Congress listens to the advice of our Naval Board, the drop of the United States to the low rank of fifth in naval strength is as certain as the ebb and flow of the tides and the rise and setting of the sun.

And what then?

The Scientific American is opposed on principle to the forecasting of possible hostilities with powers with which the country is on friendly terms; but in the present article such a forecast seems justified as proving the disastrous results which might follow from our neglect to provide a navy equal to our needs.

Let us suppose that two years from now Great Britain, estranged by our breach of faith (in the event it should not be rectified) on the canal tolls question, agreed to maintain an attitude of neutrality, while Germany, by the purchase of a base in the West Indies, challenged our Monroe Doctrine in its relation to the security of the Panama Canal. Let us suppose that, released from anxieties at home, Germany dispatched her whole first line of twenty-six dreadnoughts, and her second line of fifteen pre-dreadnoughts (including all ships dating since 1901) to the Caribbean. Where should we stand? Against her twenty-six dreadnoughts we could oppose twelve; against her fifteen pre-dreadnoughts we could oppose sixteen of the same date. Can anyone suppose that our first line could prevail against one of more than double its strength? And with the ships of our first line sunk, captured, or fleeing for a home port, what would become of our older ships, when the victorious first and second line of the enemy joined forces to crush our remaining second line, composed of "Connecticuts," "New Jerseys," and "Maines"?

And suppose Japan, smarting under the sting of our Asiatic exclusion, seized the opportune time, and swept down upon the Philippines, Guam, Hawaii, and, with no fleet to cut her lines of communication, established a base upon the Pacific Coast, and began to land her veteran troops of the Russo-Japanese war. That would be a startling object lesson in the necessity for the provision of adequate sea power by a nation so situated as our own—an object lesson, the meaning of which the people, even of the States most remote from the sea, and most opposed to the growth of our navy, surely would not fail to grasp.

Meteorological Service in the Caribbean

THE next agricultural appropriation bill will probably provide for the establishment of about sixteen meteorological stations in the West Indies and elsewhere about the Caribbean Sea, under the direction of the United States Weather Bureau, for the purpose of maintaining an efficient storm-warning service in that part of the world. The need of such a service will, of course, become especially urgent with the opening of the Panama Canal. The first extensive meteorological service in the Caribbean was established by the Weather Bureau in 1898, primarily for the protection of the American fleet during the war with Spain. Shortly after the war most of the regular observers were recalled, and the work was continued on a small scale by native observers, cable operators, and the like. In recent years a telegraphic weather service has been maintained only during the hurricane season. The new stations will telegraph twice-daily observations throughout the year, and wireless telegraphy will be employed at places where the regular telegraph facilities are not adequate. A central observatory will be established in the Canal Zone. Wireless weather reports from and to vessels will form an important feature of the new service.

Development of the Parcel Post

THE last annual report of the Postmaster General, published in December, states that during the first six months of the parcel post (January to June, 1913) approximately 300,000,000 parcels were handled, and of this number more than 2,500,000 were insured. Insurance rates were readjusted on July 1st, so that insurance up to $25 costs only 5 cents, and from $25 to $50, 10 cents. A collect-on-delivery service was established July 1st; charges up to $100 are collected for a fee of 10 cents. Increases in maximum weight limits and reductions in rates of postage for certain zones have twice been made since the parcel post was established. Nothing could better justify the existence of the new service than the fact that twenty million rural dwellers now have a house-to-house collection and delivery of parcels; a luxury once peculiar to cities and towns. An important step now in contemplation is the consolidation of the third and fourth classes of mail. Books will be admitted to the parcel post on and after March 16th, 1914.

The Kaibab and the Coconino National Forests adjoin each other. Yet it takes from two to three days to go from one to the other across the Grand Canyon of the Colorado.

The Leinert Liquid Weigher

To the Editor of the SCIENTIFIC AMERICAN:

In your issue of January 24th, in a short paragraph describing the Leinert liquid weigher, you state that this apparatus "consists of a pair of equal-sized tanks so arranged that when one is filled up to a standard level, it automatically shifts the feed to the second tank." This is an error, as when one tank is filled to a definite weight, it automatically shifts the feed over to the second tank.

New York. THE LEINERT LIQUID WEIGHER CO.
W. LEINERT.

How to Use Old Decayed Elms

To the Editor of the SCIENTIFIC AMERICAN:

Knowing of the ravages that certain beetles and pests have been making with the grand old elms in Massachusetts and other nearby States, may not the following suggestion prove of advantage to owners of trees so killed or dying?

When the owner of such valued trees sees that they are going to die and that nothing can be done to save them, instead of cutting them down, allow them to remain as before. At their base, after careful preparation of the soil, plant a great abundance of Virginia creeper or woodbine, or some rapid-growing vine that will stand the winter freezes. In time such growth will entirely cover the tree, reaching to the farthest limits, and instead of having a bare skeleton of the past beauty, it will again bloom with a grandeur not before known.

Possibly some vine or creeper can be found that will prove much better for the purpose than the two mentioned. The State authorities could well give this careful thought, and following intelligent experimenting, again beautify the remains of past glory.

Los Angeles, Cal. PIERSON W. BANNING.

Snow Removal

To the Editor of the SCIENTIFIC AMERICAN:

If a road-maker with tons of earth to dig away in the shortest possible time should propose to do the job with hand shovels he would not be likely to receive the contract. Yet this antiquated method is regarded as sufficient when it comes to clearing a great city of snow! And why? Probably because it has never occurred to anyone that more effective means might be devised. And yet it would seem perfectly feasible to apply to snow removal something of the modern methods used in removing dirt. A power shovel, mounted on a motor truck, operated by the same power that operates the truck, would seem not difficult to invent. Horse ploughs that pushed the snow from the middle of the street, leaving it in a continuous high ridge along the sides, could then be followed by such power shovels to load the snow into wagons. Without figures at hand it is impossible to say with accuracy how much faster such loading could be accomplished, but it is evident that it would be many times speedier than hand shovelling. And a power shovel would be able to handle frozen snow as readily as loose snow.

The objection will be raised that the present slowness is caused not alone by the men; that sufficient horses and wagons cannot be procured for swifter removal. This raises a second consideration; the possibility of greater co-operation between the city cleaning departments and the street railway companies. Why should not the latter's rails and power be used to aid the city by hauling the snow wagons across town? It is as easy (or, if not, it could readily be made easy) to hitch a wagon behind a service car as behind a horse. Thus the horses, having a shorter haul—only from the point on whatever avenue is being cleared to the nearest cross-town line—could do more hauling, and any given wagon would make several times the present number of trips. Of course this would involve some inconvenience to cross-town passengers; but such power-hauling might be resorted to only out of rush hours, and at night.

And in another way the railway companies could aid. At present a plough or a brush runs down the tracks, throwing the snow into the roadway for removal. Thus the amount of snow in the roadway is doubled, and half the snow in the street is handled twice. What would Col. Goethals have thought of a proposal to throw the dirt of the Culebra cut into some other part of the canal! Surely it ought not to be very difficult to construct a "plough" on the vacuum, or other suction principle, which, started out as soon as the snow began to fall, should draw it up and pass it through a pipe to a trailing car or cars of the "gondola" type—"coal cars" commonly called. It would not be necessary for the railway company to own these cars, as they could doubtless be hired for the occasion from the steam railroads.

It may be said that the expense of such methods would be prohibitive. That may be questioned. There would be a great saving in the hire of men; if not through a reduction in the number of men, it would certainly come in the number of hours of work. This would offset the expense of equipment. And it cannot be urged that this equipment would be used only after the heavy falls of snow that occur rarely. Even after a light snow vast piles are accumulated at intervals. The power shovels would remove these piles instead of the long ridges. And, even if the item of expense is still brought up, the loss to the city by street delays and congestion is too great to allow the argument to have much weight. Certainly when "power" has been so successfully applied to all other engineering problems to supplement and expedite hand work there is no need to lag behind here. And the removal of snow from the streets of a vast city is, in a way at least, an engineering problem which can be solved largely through the application of "power." P. A. HUTCHINSON.

New York.

An Improved Box for the New York Fire Alarm Telegraph

By Herbert T. Wade

FIRE alarm telegraph apparatus, in the opinion of many electrical engineers, has failed to keep pace with other departments of the application of electricity, notwithstanding the fact that upon its operation depends the safety of life and property. In this connection the fire alarm telegraph can be appropriately compared with railway signaling, where absolute sureness of operation must be provided and failure absolutely obviated. Indeed, the analogy could be pursued further and the similarity of circuits, their location and operation exposed to conditions of weather and temperature, their lack of attention requiring automatic operation, and their infrequent and irregular use, could be emphasized.

Accordingly, progressive electrical engineers interested in fire alarm telegraph are paying more attention to railway signaling and endeavoring to apply some of the solutions of problems that have been achieved amid the rapid development of this art.

But this involves a comparison between what is best in modern fire alarm telegraph practice and theory rather than with actual conditions as they exist to-day in many cities, and particularly in New York, where circumstances are such as to compel the reconstruction of the fire alarm telegraph as rapidly as appropriations are available. In this reconstruction, which for lack of means is taking place piecemeal, it is necessary to provide new elements of the best quality that will fit into the final scheme, yet at the same time will work under present conditions. There are on the market fire alarm boxes of the non-interfering and succession type, which, under good conditions of maintenance and especially with proper circuits, can be operated so as to eliminate the interference of two or more boxes operated simultaneously on the same circuit, but it must be remembered that in any city, and especially in New York, the status of the underground conductors frequently changes and that faults due to various causes, crosses from high tension electrical conductors, and other failures, are likely to develop. While in New York in particular not only are the present cables and circuits in the main badly arranged and maintained, but often as many as 50 boxes, and most of these of an antiquated and ineffective type, are placed on one circuit where 10 or 15 at the most would be considered good practice.

With such conditions in mind and new boxes required for natural extensions as well as for much needed replacements, it occurred to Mr. Leonard Day, sometime chief of the fire alarm telegraph bureau of the New York Fire Department, that a box should be developed in which all the features of the best non-interfering and succession boxes should be preserved, but in addition there should be considered further protection in view of the many defects which exist in the present circuits and which in less number might reasonably be expected under any future circuits installed under more effective conditions and of better materials and design.

It will be recalled that the making and breaking of a circuit for sending an alarm signal from a box in a fire alarm telegraph is produced by the revolution of a disk notched at its circumference, so as to afford teeth which engage a follower operating the circuit-breaking mechanism proper. The number and spacing of the teeth on the circumference of this wheel gives the signal of the individual box. Thus, if there is one tooth followed after an interval by two, and after a second interval by three, the signal 123 will be sent in to the central station. This wheel revolves by clockwork when the hook in the street box is pulled by the person sending the alarm, and makes a certain number of revolutions. The circuit thus broken and made affects a sensitive relay at headquarters, and this actuates a second circuit connected with the recording and indicating mechanism, so that the appropriate signal can be sent out to the gongs and indicators in the fire houses on other circuits.

With several boxes on the same circuit it is quite conceivable that two or more boxes might be pulled simultaneously, as has been said, and the signal either be totally destroyed or come in badly jumbled, or in case the circuit is broken, no signal transmitted at all.

In the new New York box developed by Mr. Day and Mr. E. A. Faller, the first revolution of the wheel tests out the circuit and, if it is perfect, the ordinary transmission over the metallic circuit takes place. If, however, the circuit is faulty, the line is automatically grounded on the side where the fault occurs and the signal is sent to headquarters through the ground and over the part of the line that is in good condition. This is accomplished by having an armature released after a single revolution and then by a snap switch connecting the circuit to the ground. The operator at headquarters in the meantime has received a danger signal showing that the circuit is broken, and he immediately turns down a knife switch, putting on to the particular box circuit indicated a powerful split battery sufficient to overcome any resistance, so that the current properly interrupted by the contact wheel can be returned through the ground and the signal received in the usual way. Thus it will be seen that whatever the length of the circuit or the number of boxes, it is possible in case of a break or failure, to use the ground with the portion of the circuit intact, the only contingency not provided for, and that very remote, being where a box between two faults is cut off from the central station.

Another important feature of the new box, and one which is common to all the essential elements of the reconstruction of the New York fire alarm telegraph, is that these boxes are absolutely interchangeable. Should a street box be impaired, a mechanician can be dispatched at once carrying a substitute box in a small case, and it is the work of but a moment to remove the mechanism of the box that is out of order and replace it with one in proper condition. This obviates the unsatisfactory and inefficient method of street repairs and insures better work at the instrument shop at the central station.

The new box is remarkably simple in its construction, and is so arranged that large quantities can be made by proper and modern mechanical methods. The fundamental patents on the Gamewell non-interfering succession box, which has been largely used throughout the United States, expired on February 14th, 1913, so that it is possible to make use of all desirable features of this well-known instrument, but, at the same time, the New York box is distinctly in advance of any previously constructed, and its installation in sufficient numbers will prove most valuable in the scheme of reconstruction now in process. This reconstruction of the New York fire alarm telegraph involves the provision of new central stations in three of the boroughs, new switchboards and other central station apparatus.

Barranquilla to be Made a Seaport

A LAW has been signed by the President of Colombia providing for the opening of the bar at the mouth of the Magdalena, in order to give sea-going vessels access to the city of Barranquilla, the commercial metropolis of the country. At present goods and passengers bound for Barranquilla are landed at the makeshift port of Savanilla, or Puerto Colombia, which is an open roadstead, and requires one of the longest piers in the world to connect the shore with water deep enough for berthing vessels. A narrow-gage railway runs thence to Barranquilla. The new channel in the Magdalena will admit vessels drawing 30 feet of water, and suitable piers and warehouses will be erected at Barranquilla. This city is the starting point for the flotilla of river steamers which run up the Magdalena—the first stage in the most traveled route to Bogotá.

Citrus By-Products

THE problem of utilizing waste oranges and lemons has recently been studied by the U. S. Bureau of Chemistry with interesting results. It is found that lemons which have previously been discarded will yield from 15 to 60 pounds of citric acid per ton, so that at the prevailing market rate of the acid these culls are worth from $5 to $25 a ton. Other promising by-products are the essential oils of orange and lemon, 60 per cent of which can be recovered by methods recently devised. As much as 6¼ pounds of essential oil has been obtained from a ton of fruit, and it is worth from $2.50 to $5 a pound. The gross maximum income per ton from the best quality of culls would approximate $45. It is understood that a number of companies are considering the manufacture of these by-products.

Dr. Bell's Contribution to Radium Technology.—In the SCIENTIFIC AMERICAN of September 12th, 1903, there appeared a letter from Dr. Alexander Graham Bell, in which he suggested the imbedding of radium in bodily tissue as a curative agent for deep-seated cancers. This is probably the first suggestion of a method of treatment which is now in vogue among medical men.

The Biggest of French Dirigibles

By Carl Dienstbach

ONE of the most vexing problems of aeroplane design is to minimize the air-resistance of the many bracing wires or cables. In dirigible design inventors originally worried still less about the ropes by which the car was suspended from the gasbag than early aeroplane experimenters about the "wiring" of flying machines both laboring under the erroneous impression that compared with the supposedly enormous resistance a balloon or even a large plane offered to propulsion, that of a thin rope or wire was trifling. Modern aerodynamic research has changed this view. Air in motion has been photographed, and it has been discovered that around a properly shaped balloon or plane air will so smoothly part and close again that it will escape easily without impeding the moving body. But a rope or wire will always push the air along bodily. Who has not wondered about the grip of the wind on an ordinary signal halyard, if one tries to straighten its curve by pulling? In the wake of a long thin cable the wind is all broken up into eddies, and if there is a bundle of wires or ropes, this effect is so aggravated that the air seems to be eventually "raked" along almost like so much hay. Practice has proved this no less than theory. When the writer once complimented Major von Parseval on the picturesque appearance of his "full-rigged" airship, he protested that the waste of power due to this very beauty was extravagant

Little attention was at first paid to the fact that even in the first rigid dirigible of 1900 Count Zeppelin had incidentally reduced this trouble to a minimum. It was little wonder that no sooner did the Zeppelins cease to remain badly under-engined compared with other dirigibles of corresponding displacement, than they began to attain speeds undreamed of in "lighter than air" machines. By an ingenious improvement of the original suspension the Parsevals soon managed to follow suit to a degree, because their outlines, showing only envelope and one small car, were also simple But French designers, clinging to unpromising types of large suspending stiffening frames, never equaled German speeds. Not even in details did they betray an attempt to reduce resistance against propulsion, a photograph of a French car showing a veritable jungle of exposed framing

Germany's "Gross-Basenach" type of army design, though its suspended stiffening frame was carefully incased in cloth and made of a slender streamline shape from the outset, has on the other hand recently fallen into a certain disrepute French manufacturers faced no easy problem when the government called on them to equal the speeds of Zeppelins, finally realizing that strong as they were in aeroplanes, an entire absence of speedy dirigibles might be fatal

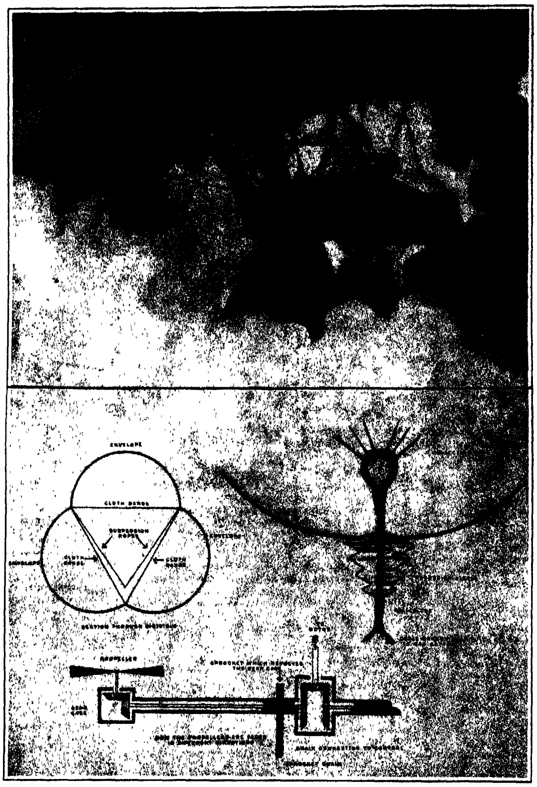
While experiments with a French rigid airship, the "Spiess," essentially a frank Zeppelin imitation, were progressing with a slowness dictated by the fate of the British "Mayfly," the Spanish engineer Torres came to the rescue. Some ten years ago he invented a fundamental improvement in non rigid airships. Laboring under the inherent difficulty of the tremendous outlay required to demonstrate a new idea in dirigibles on a scale large enough to be conclusive, which only Zeppelin was able to conquer, he offered his invention to the French Astra Company, after a futile attempt at embodying it in a Spanish dirigible of pygmy dimensions. They tried it at least on a practical scale by building after his plans one of the small so-called "vedettes" (short-range scouts) for the army, of some 1,500 cubic meters displacement The result was an unqualified success. The modest "vedette" was able to play with the big crack cruiser "Colonel Renard," of over 8,000 cubic meters, which had won the race for dirigibles at the first aeroplane meet at Rheims.

The next Astra-Torres was not lacking in size (8,000 cubic meters). It was built for the English government simultaneously with an advanced Parseval of similar dimensions, which it easily surpassed, developing well over fifty miles an hour at the official speed tests. This lesson was not lost, and now the first mammoth Astra-Torres of 23,000 cubic meters for the French government is nearing completion. It is expected to beat the new Zeppelins, because it mounts 1,000 horsepower engines on 5,000 cubic meters less displacement, thanks to the weight saved in dispensing with the rigid frame (the whole structure weighing only 16 tons), yet the rakish slenderness (the Astra-Torres measures 110 meters in length by 19 meters greatest beam) of a rigid hull and its unchanging shape, which Count de la Vaulx, in piloting the "Spiess," found such a blessing to the helmsman, have also a say in that matter.

The wonderful invention of Torres, on which such high ambitions are based, was very simple and obvious. That von Parseval did not make it was a wonder, as he virtually had it in his hand when establishing his elaborate tackle inside the gas space for controlling his airbags. It shows strikingly what constitutes the true inventor. Torres simply conceived the immense advantage of bracing a dirigible inside the gas space, which sheer habit of early ballooning had forbidden. This conception is indeed fundamental and involves the essential superiority of the dirigible over a mammoth aeroplane. Both types need an increasing amount of bracing as their size grows larger. But the necessity of exposing the braces, whatever they be, to the supporting air current in the aeroplane, whereas they can be all safely stowed away inside the streamline, gas-inflated body of a dirigible, eventually most curiously reverses the speed relations of aeroplane and dirigible. A mammoth aeroplane may be said to be just as much slower than a dirigible as a normal aeroplane is faster. The essence of the Torres invention was shown by the writer in the columns of this paper in his study of the dirigible of the future in 1911, where not only bracing is seen criss-crossing the interior of the hull, but where cables are run through the very gas. Just as von Parseval did not see that his suspension could be placed within the gas as easily as his airbag control, Torres did not see that an empty folded gas container was not a necessary condition of running ropes through the space later occupied by the gas. The idea of employing a "smoke helmet" or a modified diving suit to attach such ropes anywhere right in the gas space of a rigid dirigible, after inflation, would seem most obvious, if it did not involve the unused chance of doubling the strength of a Zeppelin, with all its consequences of saving dead weight and gaining speed. The simplest way to describe the Astra-Torres is in referring back to the study of the airship of the future mentioned above, where a rigid quadrangular structure divided the interior of the cylindrical hull. In the Astra-Torres this same structure is made triangular, equilateral, with the base line on top, and of course of flexible cloth bands, connecting the three principal longitudinal seams of the envelope. It fulfills the identical purpose of taking part of the supporting upward pressure of the gas off the side of the hull and transmitting it straight down; as the French say, it makes the envelope "labor" less. Along the upper corners of this triangle a system of suspension ropes is attached which much resembles that of the old Parsevals in its rapidly diminishing ramifications; only the ropes of course do not bear against the outside of the envelope, but converge in straight lines through the gas space, and to facilitate their egress to the air the few final cables are first caught from both sides in a "collecting ring" to which a short vertical cable (there are ten for each car) is attached, which passes through a protecting ring in the bottom of the envelope and on the outside branches again into two diverging cables running to the two sides of the cars. For greater strength they are fastened to both sides at the bottom. For some distance they are incased in an "accordion" sleeve or hose outside the hull, which communicates with the gas space and is glued to the cable at its sealed lower end, preventing escape of gas under pressure, yet permitting that amount of play for the cable which is necessary in a flexible, elastic structure.

The internal bracing being too simple to keep the envelope cylindrical (a more complicated system might be in imminent danger of getting entangled while the empty envelope is laid out for inflation), the hull of the Astra-Torres shows the characteristic shape of three separate bulging ridges, giving an unpleasantly large outside surface, which, with its frictional resistance, is regarded as a lesser, necessary evil. Attaching ropes after inflation would obviate it. The general outlines, two cars with stiffened funnels through the envelope to observation and gun platforms on top (riding there on a sort of "saddle frame"), the concentration of all steering and stabilizing planes at the poop of the hull, are obvious adoptions from the Zeppelins, while the accompanying detail of a car shows the best features of Parseval practice, such as two motors for each "Chenue," of 250 horse-power each, each driving its own screw, improved propeller mountings of small air resistance. There is the well-tried Astra spring mounting for the motors and the convenient Astra "bridge" for the captain and his staff, but it is

(Concluded on page [illegible].)



Details of the mammoth Astra-Torres.

Her gas capacity is 23,000 cubic meters. Her engines deliver 1,000 horse-power Her length is 100 meters The gas bag is braced within by cloth bands This bracing transmits part of the supporting upward pressure of the gas straight down. A system of suspension ropes leads down from this bracing, the ropes being first caught from both sides in a collecting ring to which a short vertical cable is attached which passes through a gasket in the bottom of the envelope.

How to Leave Yourself at Your Tailor's

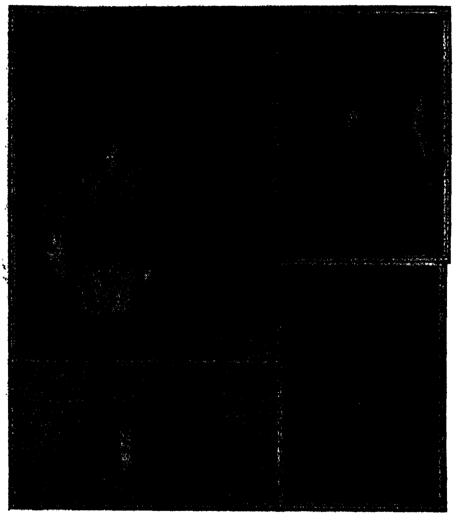
WHEN your measure is taken by a tailor he lays his tape about your chest, your waist, along your arms and your legs, in accordance with a system which tradition has laid down. However carefully he takes his measurements, the clothes must be tried on at least once and even several times if you are a very particular man. It would be more convenient if you could leave yourself, as it were, at your tailor's and proceed about your business, knowing that when your clothes are delivered they will surely fit you.

This paradoxical achievement is the fundamental idea of a German invention which has been introduced in America by a well-known New York tailor. The German inventor has actually devised a means of creating your artificial double, which your tailor uses exactly as if he had your own person to drape.

First of all you slip on a cheese cloth or linen coat, whereupon your tailor proceeds to wrap gummed paper over you with a special contrivance. He wraps the paper around your waist, passes it around your shoulder and sees to it that the edges overlap. When every part of your trunk is incased in wrappings, like an Egyptian mummy, the first stage in the preparation of your artificial double has been completed. The wrappings dry very quickly, and become hard and impervious to air. When they have reached that condition, the wrappings are slit up the back, as one of the accompanying illustrations shows. A cast of your trunk has been obtained as it were, which is peeled off like an orange skin. The wrappings are then placed upon an inflatable rubber bag of the proper shape and fastened in place. Next the rubber bag is blown up, and the wrappings are filled out and assume the exact shape of your trunk. Your artificial tailor's double has been created.

Once your measure has been taken in this novel and very accurate way, you may cable your order for a suit of clothes from Kamchatka with the certainty that when they reach you they will fit you as if you had tried them on.

The device with which the wrappings are applied is very simple. Its details are very completely revealed in one of the small illustrations published herewith. A reel of special paper passes under a guide roller, past a wet sponge and over a serrated guiding edge. The reel, the guide roller and the serrated edge are held together by a casing which is hinged on one side, so that all the members can be taken apart.



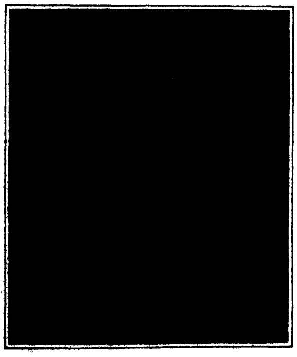
A way of creating an artificial double of yourself for the use of your tailor. You are wrapped in gummed paper, the wrappings are cut at the back and peeled off, and the shell of yourself thus obtained is placed over a rubber bag which is blown up and thus assumes the form of your trunk.

Another Automobile Head Lamp

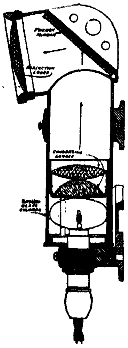
ALTHOUGH automobile engineering has progressed marvelously during the past few years, the fact remains that until very recently comparatively little attention has been paid to lamps and lighting systems—barring the introduction of electricity as an illuminant, of course. We have better illumination of objects as viewed from behind the driver's controls, what with high-power tungsten bulbs and parabolic reflectors, but the numerous unsuccessful attempts that have been made to control the blinding glare that is such a menace to the operators of approaching vehicles makes plain the inherent defect of such systems. Now, however, there has been placed on the market a radically different type of automobile head lamp in which the inventor has sought to eliminate the glare by the simple expedient of controlling the beams of light and confining them in such a way that they are projected in nearly parallel lines. Thus, by placing the lamps themselves rather lower than is usual and directing the light beams slightly downward, so that those approaching the lamps, even on foot, find it impossible, without glancing directly along the projected beams, to be blinded by the "flash" of the projecting lens, the object is attained. The secret of the success of the lamps lies in the fact that the circle of light projected has an absolutely sharp edge even to the limit of projection. The projection renders objects distant about an ordinary city block and a half quite distinct, and in this connection the inventor points out, it is the quality of the light rather than the quantity that is of greatest importance.

As already has been explained, the construction of the lamps is radically different from anything else of its kind, a fact which is made plain by the accompanying illustration and cross-sectional drawing showing the bulb and lens positions. The principle, be it added, is almost exactly akin to that of the side-walk projector, which a short time ago was in such vogue as an advertising medium.

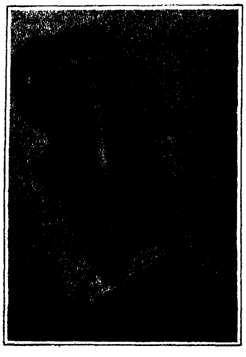
The body of the lamp is tubular and a fairly large mushroom-shaped tungsten bulb fits into an Edison socket at the bottom. A condensing lens is placed directly above the bulb and above that again there is a double combination projecting lens which directs the light against a French reflector set at the proper angle in the hood to reflect the beams through a plano-convex lens. The bulbs consume approximately four amperes when connected in parallel. A switch to connect them in series for city driving is provided.



The headlights may be secured to the radiator by means of long bolts.



Arrangement of the lens and reflector.



Added to the searchlight beam there is a widely diffused illumination.

In the tubular portion of the lamp body immediately surrounding the bulb and lens system, there is inserted a ground glass cylinder through which a soft, diffused light filters and partly illuminates the front of the car. Obviously, the amount of light diffused can be varied by altering the characteristics of the ground glass cylinders.

As the picture makes plain, the lamps are attached to the radiator of the car through the medium of long bolts running through it; owing to their lightness, it is stated that vibration can cause no harm to the comparatively delicate radiator. In another style, provision is made for attaching the lamps to the dash in the orthodox manner

A Far-reaching Trade-mark Decision

JUSTICE VAN ORSDEL of the Court of Appeals of the District of Columbia has handed down a decision in the Asbestone Company, appellant, versus the Philip Carey Manufacturing Company, appellee, patent appeal No. 885, in which he holds in a trademark opposition that where the name of an "individual, firm, corporation or association" is sought to be registered, the right of opposition is statutory; that proof of actual damage is not required, and that applicant need not be engaged actively in the business for which it was alleged it was incorporated; accordingly, he sustained the opposition

This decision will not only extend to opposition proceedings, but will open a new field for the rejection of trademark applications by the Patent Office as well as provide for the registration or entry either officially or otherwise of corporate names in the Patent Office so they can be utilized by the Patent Office as references against an application for registration. It is probable that it will be necessary for the corporation to file a certified copy of its articles of incorporation or some other certified evidence of its corporate existence, so the Patent Office can utilize the material as a reference

If the corporate existence is sufficient for purposes of opposition it is not going too far to say that it will also be a ground for cancelation proceedings. With the enormous number of commercial corporations whose titles or corporate names include high-class trademark matter, it is manifest the field of search by the Patent Office will shortly be greatly enhanced.

Coal Smoke as a Cause of Cancer was the subject of a paper presented by Sir William H Bennett at the recent Smoke Abatement Conference in London. Starting with some observations by C. E Green to the effect that there was a distinct relation between the occurrence of cancer and the kind of fuel used for domestic purposes, he detailed the results of investigations on this subject in Nairnshire, the Orkneys, and elsewhere The incidence of cancer was found to be limited to regions where coal was the staple fuel, whereas where peat was used, cancer was almost non-existent. The main exception to this statement is that a comparatively high cancer rate is found in certain peat-burning districts where the peat is a hard, black substance, burning with a long flame, not smoldering as does ordinary peat. A large sulphur content in the fuel is associated with the occurrence of cancer. The speaker pointed out that if these results were confirmed, they would form a terrible indictment of coal as an ordinary fuel.

The western lava bed in motion.

EVER since assuming my duties four years ago at this Kagoshima School, I have found Sakurajima to be a favorite subject of discussion among the citizens of this place. We had frequently imagined what would take place if the dormant volcano in the bay were to reawaken to the activity which it displayed in 1779, and always with some misgivings as to our fate if such a dread disaster were to occur. Ever since the eruption, vulcanology has been the only popular topic of conversation, and fortunately we have gained not a little knowledge from the visits of Dr. Omori and other scientists. It is my belief that a selection of this gossip will be of more interest to American readers than an eyewitness's chronicle

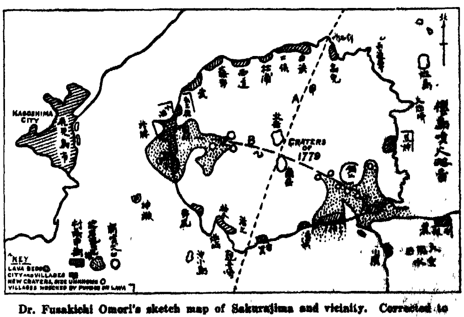
First of all, could the eruption be predicted? To this query I will say that it was, and it wasn't, foretold Dr Omori, who is a firm believer in the 60 to 65-year period of volcanic activity, has put himself upon record as having urged the purchase of a new seismograph upon the governor of this prefecture as early as last summer A bill for the $70 representing the cost of such a perfected instrument was voted down in the end, by a thrifty prefectural assembly As this year fell within the period of activity for the Kirishima, Sakurajima, Kaimondake volcanic chain, Dr Omori expected an unusual eruption at some point in the range Then again, as January 10th and 11th were marked by many earthquake shocks which continued up to the moment of explosion, the populace, especially the 21,000 Sakurajima islanders, were anticipating danger, at least a great quake On January 11th, the hot springs at Arimura village rose three feet and the water was unbearably hot. Smoke too, in fine lines invisible from Kagoshima city, was often noticed on this day, so that refugees first left the island at about 9 P M. on the night of the 11th. Not a few islanders and others were waiting for an eruption, although they could not bear to put their fears into words The head men of the various island villages frequently telephoned over to the Kagoshima Meteorological Station, but were always informed that the earthquakes were non-volcanic in character. At this point some one will say that common sense should have guided the weather prophets more wisely. But the truth seems to be that they pinned their faith firmly to the records of the antiquated seismograph at the observatory, and failed to discover the true center of the seismic disturbances. Hence, the eruption was vaguely anticipated by the best-posted scientists, and by the many islanders, all of whom escaped but two, yet it was not foretold by the weather observatory. In a sense, an imperfect seismograph must be condemned as affording no protection.

Then again Dr. Omori at Tokyo, and my colleague, Jira Sasamoto, Esq., lecturer on mineralogy, were both able to foretell the issue of the eruption which did take place on the 12th, and to declare that the city of Kagoshima would escape serious damage. These splendidly audacious and accurate prognostications were based upon an intimate knowledge of the geology of the island, and the fact that volcanic earthquakes are never very violent. Sakurajima is a much worn cone of andesite, soft at that, and covered with layers of tufa and volcanic ash which could not resist any great subterranean force without yielding. Again, the prevailing northwest winds which blow almost incessantly until April, offered an almost certain protection against pumice showers, etc. These gentlemen also knew that a tidal wave could not rise in such a deep and narrow passage (2 miles wide, 80 fathoms deep) as that which separates Kagoshima from Sakurajima unless the mountain were to drop into the sea almost instantaneously. An old volcano like Sakurajima would not be likely to do this.

Prof. Sasamoto was consulted by the local authorities on the day of the eruption, and his conclusions were widely posted up in the city, but his influence could not stop one of the most remarkable panics in history. A professor of psychology is said to have come 900 miles from Tokyo to investigate the mob psychology of this flight. The eruption began at ten in the morning, and with very little noise, the craters on the far side coming into activity at almost the same moment, and though a few people fled by eleven, a large number waited until about three in the afternoon, and then left without making any preparations at all. This was because the mountain was then entirely veiled in fog and ashes, and hence the volcano seemed more terrible. But at least two thirds of the population remained in their houses until 6:35 P. M., when an earthquake of considerable violence caused some small damage to every house in the city and drove out the population under the scourge of fear—fear of earthquakes and tidal waves.

This earthquake shock was felt with equal violence along the projection of the line *B* running northwest and southeast in the map. Owing to the soft volcanic rock which is alone available for building purposes in this neighborhood, stone walls were much injured, especially when they lay north and south, at right angles to the shock. This, strange to say, was the only notable earthquake that took place.

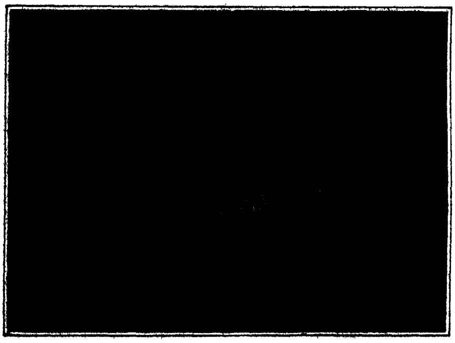
A Japanese friend once remarked to me that it was impossible to run from



Dr. Fusakichi Omori's sketch map of Sakurajima and vicinity. Corrected to February 4th, 1914.

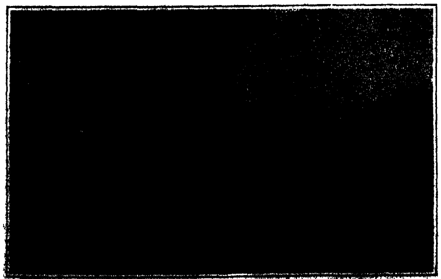
A. Line of the Kirishima, Sakurajima, Kaimondake volcanic chain. *B.* Line of the Ijuin Fault. (Earthquake felt with greatest force.) At the extreme left, Kagoshima city. Opposite are the villages indicated by Japanese characters which have been wrecked by pumice or buried under lava. These are, from northwest to northeast, Akabubara, [illegible], Yokoyama, the island of Karasujima, engulfed, Arimura, Seto, Ushine on the mainland, and Kurokami to the north. The lava-flow from the southeast craters has connected the island to the mainland.

The western and eastern craters on January 24th. Steaming lava is seen low down in the right-hand corner



View of the eastern lava beds covering the site of the village of Arimura, southeastern Sakurajima. The lava has been bifurcated, as shown from the map on the previous page, by the small knoll to the left

Ushine village on the mainland. This picture was taken amid thickly falling ashes so that distant points are not seen. The village homes are visibly covered with volcanic deposit



The eastern craters and the ash-buried village of Kurokami.

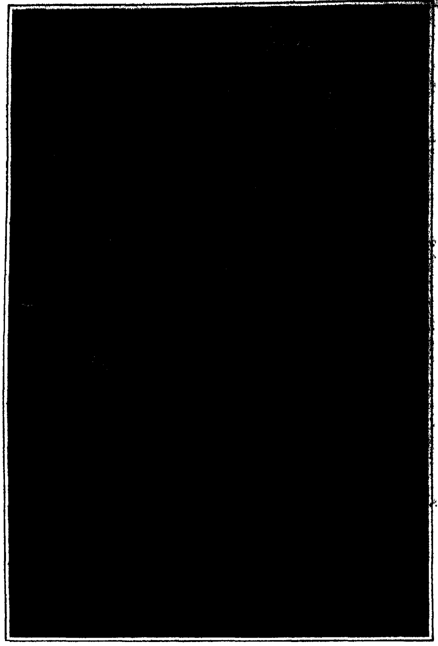
Sakurajima dormant Photographed from the hills behind Kagoshima.

danger in battle but that it was his duty to leave his house in an earthquake Among the refugees there was no wailing and no fainting of women such as might occur elsewhere but these people did not need to shout or discuss their plans, they were all mastered by the one thought of their personal safety Yet there was little selfishness and on that day none of the last courage born of avarice no pilfering And those people who determined to stay after the earthquake were gradually driven off by appalling electrical phenomena that increased during the night, or else warned to leave the city by the police and soldiers who came in boldly to watch over the deserted city It seems very doubtful if one thousand persons out of a population of 70 000 spent the second night of the eruption within two miles of the city

As to the characteristics of the eruption it was pre-eminently an ash eruption at first The force of the explosions was not great yet as there was so little resistance ash and clouds were carried to at least 20 000 feet and the eruption seemed to be more violent than it was and very short-lived since there was no check upon it On the other hand no glass whatsoever was fractured The electric displays were unbearable and the thunder deafening However there was almost no moisture, only a heavy thunderstorm of three hours on the second night that affected all of the island of Kyushu Since this time there have only been two short rainfalls Hence the skies were not obscured owing to the wind and the moonlight was a great comfort to the refugees On the other hand, the lava flow has been unusually great for a Pacific Ocean volcano in the modern period

Lava began to flow about 8 o clock on the evening of the 13th the most spectacular moment of the whole eruption and continued to flow from the western craters until January 26th On Monday January 19th the island of Karasujima was engulfed in this bed and even as late as January 24th the whole bed was advancing at the rate of a foot an hour in Dr Omori s opinion The photograph shows how rocks would roll down from the crest of the lava beds as they were pushed forward The area of the two lava beds was then estimated as totaling 10 square kilometers with an average thickness of 50 meters, making the amount of lava then emitted reach 7 cubic kilometers On the eastern side the craters are still exceedingly active, and lava continues to flow The channel between Sakurajima and the mainland has been entirely filled converting the island into a peninsula and blocking the fairway for the steamers which used to make the circuit of the island

The injury wrought by the volcano has not been confined to the island, but is very wide in those districts of Kagoshima prefecture lying to the southeast and hence still suffering from such constant showers of ashes that no photographer has been able to get clear pictures of the affected area. We are truly thankful that their loss has been our gain and that it is possible to flatly contradict the absurd telegraphic reports which first heralded the eruption to an astonished world

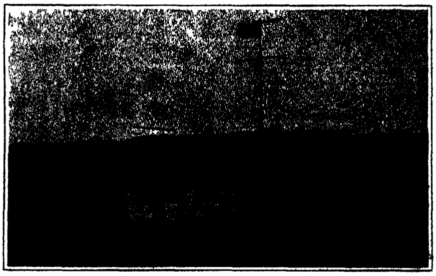


Trees stripped of leaves and houses buried under fall of rocks and ash at Kurokami village, eastern Sakurajima. The pits seen in the photograph are caused by the collapse of the houses located here.

Wireless Detection of Wireless Criminals

By V. Ford Greaves, United States Radio Engineer

A WIRELESS detective is maintained by the United States Bureau of Navigation to patrol the waters along our Atlantic coasts to trap the radio practical joker who sends out false S O S messages, to locate the station that does not observe the prescribed wave-length regulations and in general to see that order is maintained in circumambient ether This detective the motor boat Tarragon was originally designed to act as policeman for motor boats and make them observe the navigation laws Now it has been equipped with a very efficient radio apparatus in charge of U S Radio Inspector Benjamin F Wolf, and will enforce the radio laws of the United States and the London International Radiotelegraphic Convention along the Atlantic Coast.



United States patrol that enforces wireless laws.

The radio apparatus was designed and assembled under the direction of Mr. Frederick A Kolster of the Bureau of Standards Its special features are compactness and facility for quick change from one transmitting wave-length to another. The transmitting apparatus and motor generator are all mounted on a panel-board 22 inches wide by 30 inches high, as a single unit The apparatus on the back of the board projects a maximum distance of 18 inches The motor generator is operated by 20 Edison cells, which will operate the apparatus continuously on full load for about eight hours on one charge The cells are charged by a small auxiliary gas engine direct connected to a 35-volt, 35-ampere generator The spark-gap is of the quenched type A break system relay enables the operator to be "broken" or to overhear any interference while transmitting At present the normal wave-length of the "Tarragon is 300 meters. In addition to this, transmitting wave-lengths of 200 to 450 meters are provided for The change from one wave-length to another is accomplished by a single throw of a six-point switch mounted on the panel board This single operation tunes both the oscillating and open circuits to resonance, and with a slight variation of coupling, maximum radiation is obtained The wave-length change device and the method of varying the coupling are very ingenious, and were devised by Mr Kolster The receiving apparatus is secured to a bulkhead, and the operating table upon which is mounted the transmitting key folds down when not in use The complete installation occupies very little valuable space, even considering the comparatively small size of the ' Tarragon."

The installation is rated at one quarter kilowatt, and on the 300-meter adjustment delivers a little over 3 amperes in the antenna. The antenna is necessarily of the comparatively inefficient inverted V type on account of the single mast available. The maximum height above the water line is about 27 feet and the natural period of the antenna about 60 meters

A test of the apparatus was conducted while the Tarragon ' was in the vicinity of Norfolk, Va The ' Tarragon" was able to plainly hear the time signals and weather report from Arlington and the same report repeated by the Key West Naval Station The press messages from Sayville, L. I., were also copied Communication was established over a thickly-wooded country a distance of about 35 miles with the Norfolk Navy Yard Station This indicates that the equipment has an approximate transmitting range at sea by night of 150 miles and that the Bureau of Navigation may communicate with the vessel by wireless telegraphy wherever she may be along the Atlantic Coast

Comparing the results of this test with those obtained by the average commercial shipboard station rated at one kilowatt and showing an antenna current of from 3 to 5 amperes and having efficient inverted L antennæ from 60 to 125 feet above the water line it is concluded that the 'Tarragon s' radio equipment is extraordinarily efficient

Radio apparatus of the motor boat "Tarragon."

Interpreting Claims—In Hall Mammoth Incubator Company vs Teabout (U S D C) District Judge Ray, citing Winans vs Denmead (15 Howard 330) said "Unless there are limitations written into the claim, or imposed by the prior art, or by acceptance of a narrow claim in place of a broad one, in the Patent Office, in order to secure the patent, the inventor is entitled to every form in which his invention may be copied and to a broad construction." Also that "Hall elected to locate his levers and connecting rods, etc., where and as he did and to claim specifically all the several parts and cannot ask the Court to modify or rewrite his claim by ignoring any claimed element of his combination. He asserted their materiality by claiming them, and cannot be heard to deny it."

A New Way of Detecting Art Forgeries

The Microphotographic Study of Brushwork

By Prof. A. P. Laurie, Hewitt-Watt College, Edinburgh

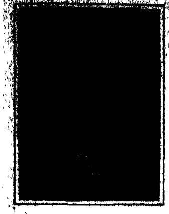


Fig. 1.—Microphotograph of head in a Watteau. No. 55 in Edinburgh National Gallery.

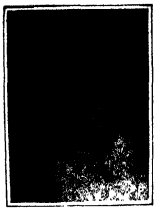

Fig. 2.—Microphotograph of the head shown in Fig. 1, but from the copy of Watteau shown in Fig. 5.

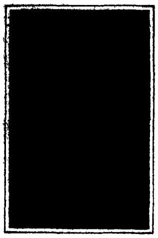

Fig. 3.—Microphotograph of face from a Pater. No. 60 in Edinburgh Collection.

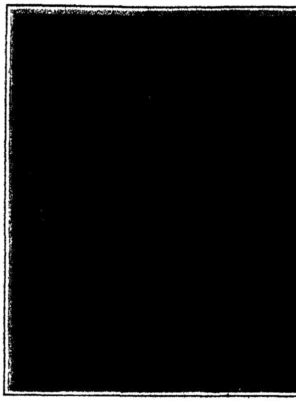

Fig. 4.—A representation of a genuine painting by Watteau. (No. 55 in the National Gallery of Edinburgh.)

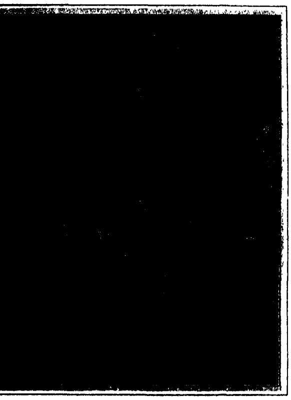

Fig. 5.—Copy of the Watteau No. 55, which is apparently handled quite in the manner of the master.

Fig. 6.—Head of old man by Teniers. No. 817 in London National Gallery.

FOR some time I have been engaged in a series of researches, with a view to applying scientific methods to the identification of pictures and the exposure of forgeries. In the first place I began by making a careful investigation into the history of pigments with a view to deciding at what dates certain pigments were used in the history of painting, as it is obvious that if we have a knowledge of this, we can very often approximately date a picture, and so decide whether it was painted at the period to which it has been assigned. These investigations were carried out by the study of dated documents, such as Illuminated Missals, Venetian Ducali, and the Coram Rege Rolls in the Record Office, London, which are illustrated with miniatures from 1500 to 1700.

By means of these dated documents it has been possible to construct a fairly complete history of pigments, and to state very definitely when certain pigments came into use and other pigments ceased to appear upon the artist's palette. In addition, I have devoted considerable attention to the microscopic study of the surface of pictures, with a view to detecting repainting and identifying the pigments in position, and also to the microscopic identification of pigments, enabling one to deal with the very tiny samples which can be removed without injury to the picture.

These methods, then, enable one to decide whether the picture is a modern forgery, whether repainting has taken place, and also to date the picture itself approximately In addition, it has been found that certain artists are accustomed to use certain pigments, so that the probability of a picture being by a given artist is strengthened if the pigment which he generally used is found upon it. It was while making these researches that I was struck with the amount of information which could be derived as to the painting of a picture, from the careful study of the brushwork suitably magnified. It is, of course, customary for all art connoisseurs to use a magnifying glass, but the information to be obtained is very much more reliable and useful if, instead of using the magnifying glass, careful microphotographs are taken of selected portions of the picture under examination.

In order to get successful results, the enlarged photograph should be taken directly on to the negative, the amount of enlargement depending on the style of the brushwork of the particular artist. As a rule, about three diameters are sufficient, but there are cases where enlargements up to as much as six diameters are of value for this purpose. By means of these photographs one is able to isolate the facts of brushwork without any confusing considerations, and one is able to compare side by side a series of such microphotographs.

Supposing, for instance, a picture is believed to be by a given artist, microphotographs of selected portions are taken and these are compared with microphotographs of pictures of undoubted authenticity by the same hand; while, if there is some other artist whose name is suggested as a possible author of the picture, microphotographs are also taken of his work, for comparison. In this way it is possible, in the case of a very large number of painters, to arrive at very definite conclusions. There are schools of painting, of course, which do not lend themselves to these methods, but, on the other hand, there are many artists whose individuality of brushwork is so marked and so characteristic as to make imitation impossible. The copyist or the pupil may imitate a master's general style, but each man has his own way of laying on the paint which is characteristic

During the time I have been investigating this method, I have been accumulating typical microphotographs of the brushwork of many of the great masters, and every day one is learning something new as to their methods, and also as to how far a man's brushwork varies, and how far certain characteristic touches remain throughout his career.

In the case of the painters of small pictures with minute figures, such as Teniers and Watteau, microphotographs of the whole of the face are usually most useful, and the enlargement may extend to five diameters on account of the minuteness of the brushwork employed by these artists. In the case of the life-size portrait painters, it is necessary to select some portion of the face into which the artist has put the greatest amount of careful work. On the whole, the eye usually gives the most information, magnified some three diameters In the case of landscape artists, the painting of foliage is usually very characteristic. At the same time, it is usually advisable to examine the picture very carefully with a view to seeing whether there is not some piece of rapid and characteristic painting on which the artist, working very freely, has shown his peculiar methods. In the case of Velasquez, for instance, it is often found in some portion of the painting of the figure itself—a piece of drapery or a tassel or a bit of embroidery being painted in with a rapid and characteristic hand.

There are also obviously certain dangers in an investigation of this kind, owing to the fact that so many of the great artists employed their pupils to do the less important parts of their painting, and therefore we must not be led astray by assuming the work of a pupil to be the work of a master. It is for this reason that, as a rule, it is safer to compare the more important parts of the painting

From the large number of photographs which I have made, I select one or two typical examples, in order to illustrate the various points. The

The Storm of March 1st, 1914, Measured in New Units

By Alexander McAdie, Director Blue Hill Observatory

IN various recent issues of the Scientific American reference has been made to the desirability of recording meteorological conditions in more rational units than those of the old scales. In the Scientific American Supplement for December 6th, 1913, there is described in detail the new methods of representing atmospheric pressure variations in per millages (or percentages with an added decimal) of a standard pressure

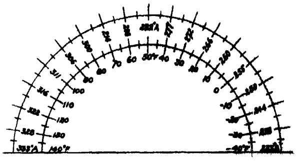
It may not be out of place to restate briefly the essential features of the new notation. First, temperature is recorded on the absolute Centigrade scale, the zero being that of the hydrogen gas thermometer, or practically 273 degrees below the zero of the Centigrade scale thermometer. We thus say "good-bye" to the Fahrenheit scale, which, serviceable for many years, has, however, now outlived all usefulness, and is practically discarded in all scientific work It may be recalled that originally this scale ran from —90 degrees, mixture of salt and ice, to + 90 degrees, the temperature of the human body, the whole making 180 degrees Later Fahrenheit made the zero of the scale the lowest temperature of the winter of 1709 in his country, 32 degrees the temperature of melting ice and 212 degrees the temperature of boiling water under constant pressure. The other scales, Reaumur's, Celsius, and Linnæus's modification of the Celsius (the modern Centigrade) may also be relegated to the past

The new zero is that of the hydrogen gas thermometer. Here the temperature is directly proportionate to the pressure There is a temperature scale known as the absolute energetic or thermodynamic scale in which the ratio of any two temperatures is equal to the ratio of the heat absorbed at the one temperature to the heat evolved at the other when heat is transferred by any reversible cyclical process whatever. Unlike gas or mercury thermometer scales, the definition of temperature does not here involve a relation to any property of any definite substance Temperatures expressed in this scale are proportional to the pressures given by a constant volume thermometer filled with a perfect gas There is very little difference between the two scales, and while there are some uncertainties in connection with the absolute zero itself there is no great error in making the zero 273 deg Cent below the temperature of freezing water For ordinary atmospheric values, we have as given in Fig. 1

In the storm of March 1st, contrary to expectation, there were no marked changes in temperature. The record at the observatory, 195 meters above sea-level, shows a gradual rise from 273 deg A to 280 deg A The record at the base station, 64 meters elevation, is practically the same There were no abrupt rises or falls. At the lower level it was colder from 4 A M until 6 A. M. than at the summit About 8.30 P M. the temperature fell about five degrees, the fall occurring at the higher level about twenty minutes in advance of the lower. Unfortunately there are no records available for various levels in the free air The wind did not shift as expected and the path of the storm was evidently somewhat west of north rather than to the east. From 2 A M. until 2 P M the wind was east-southeast, then backing to east and remaining so until 8 P. M., when it veered to southeast, notwithstanding this was the time of lowest pressure. The maximum velocity occurred at 6 30 P. M , 27 5 meters per second, equivalent to 33 meters per second (74 miles per hour) in the uncorrected velocities used by the Weather Bureau. At the time of lowest pressure, 7 35 P M, the velocity was 27 meters per second, decreasing gradually until 10 P. M. and rapidly after that. With such a marked pressure fall higher velocities might have been anticipated. On February 10th, 1909, a velocity of 32 meters per second (84 5 miles per hour, uncorrected) occurred

The total rainfall was 34.5 millimeters, and there were no unusual features either of intensity or duration. The relative humidity throughout the whole period was 100 per cent

The feature of the storm that was remarkable was the fall in pressure (Fig. 2) The lowest reading recorded in the history of this observatory (twenty-nine years), and possibly the lowest in Weather Bureau records for this part of New England (forty-four years) occurred. In the old notation the reading would be 27.80 inches (28 47 inches at sea-level). Those familiar with weather charts know that any reading below 29.00 inches is low, but even to professional meteorologists the figures do not convey a clear cut conception of the value of the fall and the significance of the reading. In the new system (see pressure charts) the reading is 941 kilobars If we take 1,000 kilobars as the standard pressure or absolute atmosphere then one sees at a glance that there was a fall of 59 kilobars, or 5.9 per cent. Suppose we call it 6 per cent of an atmosphere. If the height of the homogeneous atmosphere is approximately 8,000 meters we know at once that the storm caused the same decrease in pressure that a rise of 480 meters would give. Again, it is very simple to determine the gradient either with respect to distance or time. Thus at 2 P. M. the pressure was 961 kilobars, and at 8 P. M. 941. The difference, 20 kilobars in six hours, is in units of absolute force 20,000 bars, the bar in this case being the absolute unit of pressure. We thus have (what has long been desired) a C. G. S. atmosphere, and the values of all readings are easily comparable with other pressures, from that of ten atmospheres to the feeble pressure of radiation.



Convenient conversion scale, temperatures F. to A.

In the Scientific American Supplement for October 25th, 1913, Mr. A. F. Miller has given a very interesting computation of the equivalent weight of the air displaced in the marked storm of January 3rd, 1913. He takes as the extreme pressure readings 30.30 inches and 28.30 inches. In the new system these would be 1,026 kilobars and 958 kilobars, and the difference 68 kilobars In the old system, after some figuring and likelihood of error, one computes that over every 2,000 square inches the reduction in pressure would about equal the removal of one ton of air. In the new system one knows at a glance that the reduction was 6.8 per cent of the normal pressure whether expressed in units of weight or of force

BASE PRESSURE 1,000,000 DYNES OR 1,000 KILOBARS.

Pressure in kilobars = 1,000 +.

Barometer in inches.	.00	.02	.04	.06	.08

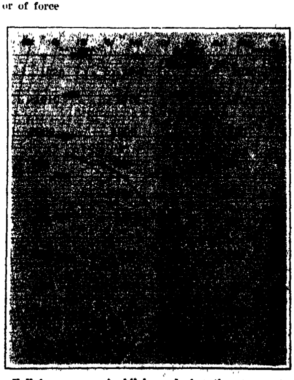
30.80	+ 43.0	+ 43.6	+ 44.3	+ 45.0	+ 45.7
30.90	+ 46.4	+ 47.0	+ 47.7	+ 48.4	+ 49.1
31.00	+ 49.7	+ 50.4	+ 51.1	+ 51.8	+ 52.4

Example: Barometer reading 29.62 inches, convert to kilobars. Tabular correction for 29.60 + 0 02 is + 3 0 Pressure in kilobars is 1,000 + 3.0 = 1,003.0.

A convenient conversion table for pressure in kilobars. (Prepared at Blue Hill Observatory.)



Fall in pressure in kilobars during the storm of March 1st. This is the first record of pressure in kilobars ever published.

Prevention of Mine Explosions by Stone Dust

RECENT elaborate experiments by English scientists show that the presence of considerable stone dust in coal mines tends to quench the combustion of "fire damp" and coal dust. This important work points the way to prevention of a large proportion of mine explosion, and it is to be hoped that the method will be tried out in all countries, and developed into the maximum efficiency.

It is universally agreed now that a mixture of coal dust and air is just as explosive as a mixture of fire damp or methane and air. The same is true of flour mill explosions, undoubtedly caused by the ignition of a favorable mixture of air and floating flour dust.

To understand clearly the preventive effect of stone dust, one must consider the mechanism of the reaction between two gases capable of combining with each other. When the temperature of part of the mixture is raised to the ignition point a few molecules unite first, but the heat produced by their union is at once dissipated through the remaining molecules. Of course if the entire mixture is suddenly raised to the ignition point by external heating the combination may be instantaneous and explosive, but if only a small portion of the gas mixture be heated the action takes place in two stages. The heat given to surrounding molecules by ignition at the initial point will cause them to unite if the mixture is right, and thus the flame will spread. As the flame spreads, however, the general temperature and pressure is raised to a point where practically all the molecules in contact unite instantly—the "explosion wave."

In a mixture of methane and oxygen there must be at least a definite percentage of methane to insure ignition. Less than that much methane in the mixture will not unite. With just this minimum percentage of methane a spark or glowing wire will cause combustion of the methane and oxygen on its surface, but the flame will not spread and no explosion will result. The point is that the heat of combustion is carried away by the excess of oxygen molecules. Excess of nitrogen or any inert gas would cool the flame in the same way.

With floating coal dust the mechanism is similar. A small flame from any source heats a little dust to the point of distilling off coal gas which forms an easily inflammable mixture with the air. The flame thus propagated heats the remaining dust and air to such a temperature that the intensity of molecular contacts insures almost complete and instantaneous combustion with explosive violence. The speed of this propagation of flame is enormous. Wheeler and Darwin measured it in one case as 1,300 miles an hour. The presence of suspended coal dust is accounted for by the jarring effect of the flame wave from an initial gas explosion. Thus a small methane explosion might be so in effect as to do little damage, but with plenty of coal dust in the galeries to be jarred into the air, the explosion may be carried throughout the mine. The problem is to dilute all possible explosive mixtures with inert materials, gaseous or otherwise, so that impacts between active molecules will be lessened and the flame cooled so that it cannot travel. Crushed shale, limestone or fuller's earth act in this way. It was once thought that such dust particles aided the flame catalytically, but experiments in England have proved beyond doubt that inert dust in the mine actually retards explosion.

It is worth noting that in the presence of a flame, coal dust, and air, the first action is distillation if the coal is bituminous, and second the burning of the gas so formed. After this flame runs some distance the oxygen molecules seem to hit the dust particles so violently that there is instant burning of the dust particles as a whole without further distillation. The preliminary slow burning followed by gradually increasing velocity and pressure and finally high pressures and great oscillations of flame are characteristic of both fire-damp explosions and coal-dust explosions. An initial fire-damp explosion may set off anthracite dust or even charcoal dust.

It is urged that care be taken to use only such stone dust as will not injure the lungs of miners. Obviously powdered quartz would not do. Also the dust must be applied as often as it becomes overlaid with a fresh deposit of coal dust of any appreciable thickness. Of course the heavy stone dust cannot be kept in the air ready for emergencies, but that is not necessary. As soon as an explosive wave reaches the stone dust, enough of it is thrown into the air to cool the explosive mixture below the burning point.

C. G. S. Units of Barometric Pressure

THE British Meteorological Office has decided to take the radical step of adopting the C. G. S. units, centibars and millibars, in place of the familiar inches of mercury in all its barometric measurements (instead of merely in its upper-air observations, as heretofore). Beginning May 1st, 1914, the new units will be used on the British daily weather maps, isobars being drawn for each half-centibar.

[illegible] PATENTED INVENTIONS

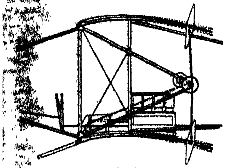
[illegible] columns are open to all patentees. [illegible] are inserted by special arrange[ment] with the inventors. Terms on applica[tion] to the Advertising Department of the [Scien]tific American.

Pertaining to Apparel.

[illegible]—CHARLOTTE MACDONALD, care of Edward Macdonald, Ossining, N. Y. This [inven]tion provides a corset having a plurality [of] vertical members, which are connected by [a plur]ality of horizontal elastic members, se[illegible] the vertical members, the horizontal [illegible] free from adjacent elastic members, [illegible] the vertical members, so that [illegible] ones may act independently of [illegible]er. The corset gives the greatest [illegible] of movement, and especially it is [illegible] for women engaged in athletic pas[illegible]

Pertaining to Aviation.

[AERO]PLANE.—D. M. CALHOUN, Clarks, La. [This in]vention relates particularly to a form [illegible] in monoplanes or biplanes in which [the fro]nt portion is essentially rigid and non-[vibrati]ng, while the rear portion is vibratory [and ha]s connected therewith a vibrator to im[pa]rt [illegible] and rapid vibrations in a vertical [illegible] The vibratory rear portion of the plane [is cont]iguous with the rigid front portion, so that the upper and lower surfaces of the com[ple]te plane are continuous, while the rear por[tio]n, which is flexible, constitutes in effect, a [illegible] propeller. The plane preferably is [cu]rved, the curve decreasing toward the rear. Vibrating of rear portion of the plane may [ex]ert a propelling force auxiliary to that of known propellers, or may be utilized alone as a propelling means.



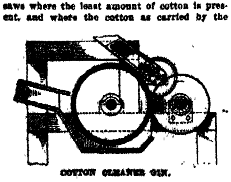
AEROPLANE.

Of Interest to Farmers.

CHICKEN ROOST.—F. SCHARDT, Arapahoe, Neb. The object of the inventor is to provide a device wherein a roost is provided, upon which the fowls may perch, and means in connection with the roost for containing chemicals or the like for destroying vermin on the fowls, and so arranged that when the perch is unoccupied, the chemical containing means will be closed, and will be opened to permit the medicinal agents to escape when the perch is occupied by the fowls.

CHICKEN ROOST.

COTTON CLEANER.—E. A. ROSIER, Sparta, Ga. The purpose of this device is to comb, card or clean cotton while the latter is passing through the gin and is being carried by the gin saws at points in the rotation of the saws where the least amount of cotton is present, and where the cotton as carried by the saws offers the least resistance to motion of the saws. By the use of the apparatus the color and general quality of the cotton are greatly improved, the cotton operated upon being as a consequence entitled to a higher grading. The engraving shows a vertical section through a gin equipped with the invention.

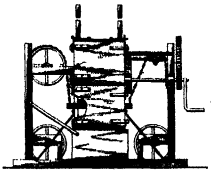


COTTON CLEANER GIN.

TRACTION WHEEL FOR PLANTERS.—E. [illegible], [illegible] North [illegible] St., Springfield, Ill. This invention relates to traction wheels for corn and other planters. It provides a traction wheel which will straddle the hills of corn [illegible]. A further object is to provide a wheel with means which will effectually prevent it from slipping.

GRAIN TESTER AND SEED SEPARATOR.—A. C. ENGELSTAD, Aylesbury?, Canada. This invention provides a portable device by means of which seeds or grain have practically the same specific gravity. Thus the device may be used for separating wild from cultivated oats. The device is made in sections and readily taken apart to permit access to the seeds which are so separated.

BALING MACHINE.—C. F. UECKE, New London, Wis. This invention is an improvement in baling machines, and has for its object the provision of a machine for compressing any desired material, as for instance, cotton, hay or the like, wherein a pressing chamber is provided, and a plunger movable in the pressing chamber, together with means for permitting the plunger to be moved manually. The accompanying engraving presents a front view of the improved baling machine.



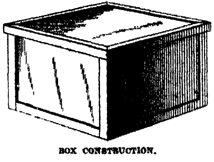
BALING MACHINE.

Of General Interest.

MANUFACTURE OF ARTIFICIAL SILK.—H. TIMPE, Weesperzijde No. 125, Amsterdam, Netherlands. This inventor employs as a starting material the protein substances which remain in cows' milk after the same has been reacted on by salts of pyrophosphoric acid or pyrophosphates, and the casein precipitated thereby has been removed therefrom. These protein substances are then thrown out from the whey, and by certain means by which the finest elastic silk-like threads may be produced of great strength and toughness and adapted for all purposes where silk is employed.

MANUFACTURE OF PRODUCTS FROM INDIA-RUBBER.—H. DOGNY, 13 Ave. d'Eylau; V. HENRI, 82 Rue Claude Bernard; and E. VEIL-PICARD, 76 Ave. Wagram, Paris, France This invention refers to improvements in the manufacture of products from India-rubber or other suitable resilient material of the kind composed of either perforated sheets or perforated and unperforated sheets of such material, which are united together and have the cavities so formed filled with gas or air whereby a pneumatic and resilient structure is obtained.

BOX CONSTRUCTION.—O. W WARD, 96 Fifth Ave., Manhattan, N. Y, N. Y. This improvement relates to the construction of cheap strong articles such as stands, taborets and the like, and also to the construction of storing and shipping devices such as hat boxes, etc. It provides means whereby devices of this character may be quickly and accurately assembled which permit a neat and ornamental appearance, the same having also the capability of being knocked down or taken apart for purposes of storing away in small places or for shipment empty.



BOX CONSTRUCTION.

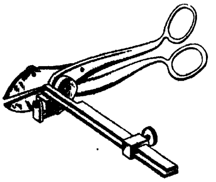
NON-REFILLABLE BOTTLE.—I. D. KELLET, 1178 Jackson Ave., Bronx, N. Y., N. Y. This invention relates to bottles, jars, etc., in the neck of which there is arranged mechanism serving to permit the outflow of liquid, but preventing an inflow of liquid. An object is to improve this class of devices whereby a container will be rendered practically non-refillable by the use of simple and reliable means.

BUFFING OR POLISHING WHEEL.—G. P. KELLER, 418 W. 27th St., New York, N. Y. This wheel is formed of a plurality of folded pieces of muslin or other fabric material. It is arranged to prevent the peripheral face of the wheel from unraveling and thus insuring long life of the wheel, and to allow using the wheel until the fabric pieces are practically used up.

Hardware and Tools.

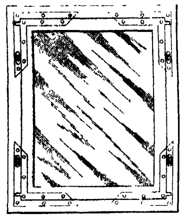
COMBINATION TOOL HOLDER.—W. L. HANE, Ocala, Fla. Mr. Hane's invention is an improvement in combination tool holders, and has for its object the provision of a simple, inexpensive holder of the character specified, for use with lathe planers and shapers, and wherein the holder may perform a plurality of functions, thus resulting in economy in both time and labor.

SHEARS.—C. F. ZIMMERMAN, Jersey City, N. J. This invention relates to shears for cutting sheet metal or for other like purposes; and has reference more particularly to shears comprising a member consisting of a blade and a handle, a second blade pivotally mounted upon said member and having an extension pivotally connected with said second blade. It also relates to the combination of shears and a gage foldably associated therewith and having means for locking the gage in an operative position, the gage serving adjustably to determine the length of material to be severed.



SHEARS FOR CUTTING SHEET METAL.

HANGER FOR SLIDING SASHES.—F B MASLEN, Moberly, Mo. This invention has for its purpose the provision of a hinge for connecting the frames and so arranged as to permit the complete detachment of the frames or the detachment at either side of the said frames to permit the said frames to swing with respect to each other In use, either side of the frames may be released to permit the frames to swing with respect to each other, and both sides of the inner frame may be released, if desired, for removing the said frame to clean it or for any other purpose



HANGER FOR SLIDING SASHES.

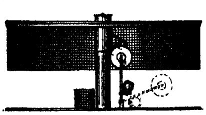
Household Utilities.

HOLDER FOR ICE CREAM FREEZERS.—F. HOSTETTER, 8905 Third Ave., Bay Ridge, Brooklyn, N. Y. Means provide for holding the freezer while the cream is being frozen, and the invention provides a holder in which the freezer may be firmly clamped in position and provided exteriorly with folded foot-boards on which the operator stands, or on which he may place a chair so that his weight will be availed of in the most effective manner in preventing movements of the holder and freezer

WINDOW CLEANING PLATFORM.—H. BOTTJER, 631 Classon Ave., Brooklyn, N. Y Among the principal objects of this invention is to provide a platform which may be adjusted to fit any ordinary size of a window and which will be strong and reliable when used in any position of adjustment with respect to the size of the window.

Machines and Mechanical Devices.

ANIMAL TRAP.—J. DE ST. LEGIER, 1st St., Hicksville, N. Y. This device is arranged so as to provide access to the trap from any direction when in set position, and to trap an animal alive and without danger of injury to its valuable fur or feathers Use is made of a base provided with upwardly-extending guiding means, a bottomless cage mounted to slide up and down on said guiding means, a supporting and releasing device for supporting the cage bodily a distance above the said base and for releasing the said cage to allow the latter to drop down onto the base, and locking means for locking the cage in trapped closed position.

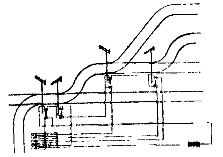


TRAP FOR BIRDS AND MAMMALS.

CARD EXHIBITING DEVICE.—H. W. HELLIKER, 1271 Tenth St., Oakland, Cal. This invention relates especially to devices for holding and exhibiting cards or the like. The particular object is to provide an exhibiting device for cards for use in connection with certain game apparatus made the subject of a previous application filed by Mr. Helliker, Serial No 730,163, and allowed April 8th, 1913, and of which this application is a division

Railways and Their Accessories.

SWITCH INDICATOR.—C. M. ROE, 315 Webster Ave, Jersey City, N J More particularly this invention relates to a means for indicating to the train engineer the position of the several switches to which he is approaching It is of advantage, in approaching a terminal, to know just what track of the terminal the engineer is coming into and be able to tell ahead of time just what curves and switches he is supposed to take This invention indicates to the operator, in entering the yard or the limits of the terminal, just what track is open to him



SWITCH INDICATOR.

BLADE FOR RAILWAY SWITCHES.—M GRIMALDI, mechanician, Rome, Italy In this patent the invention has reference to a blade for railway switches and consists substantially in that the heel of the blade is revoluble around a pivot which is carried by a support movable upon a slide plate As soon as a car has passed a switch, the blade resumes its normal position

Pertaining to Vehicles.

SPRING WHEEL FOR VEHICLES.—W J. LUTTRELL, Honey Grove, Texas In this invention the improvement relates to wheels of that type consisting of an inner and an outer section of annular form, with spring cushioning devices between the sections for use in insuring easy running of the vehicle by the spring devices absorbing shocks and vibrations.

ROAD VEHICLE WHEEL.—S H COPE, *Alma Street, Aston, Birmingham, England.* This invention has for its object the construction of an improved motor or other road vehicle wheel, of the type in which a detachable rim is employed, said rim having a radially or laterally movable segment for facilitating application and removal of the tire to and from the rim

WHEEL GUARD.—WILLIAM C PIGGOTT, London, England The guard comprises a depending guard member in the form of a leaf spring mounted in front of the front or back road wheel above the road surface, with facility of rearward, upward and preferably lateral movements, on the front wheel stub or movable axle or other part of the vehicle so that the guard member will, under normal conditions, remain in front of its wheel

Designs.

DESIGN FOR A LAMP SHADE.—L C TIFFANY, *care of Tiffany Furnaces, Corona*, L I., N Y This ornamental design for a lamp shade is in bell shape, the attractively uneven surface of the shade comprising a highly original and beautiful composition in plant life

DESIGN FOR A SET OF POLITICAL PLAYING CARDS.—M S. OLSEN, Box 558 Minot, N. D The faces of the cards employed in this ornamental design bear the party names Each card is embellished with the party emblems of heads, flags, mottoes, etc., and are numbered

---

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper

---

WE wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject matter involved, or of the specialized, technical, or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States

Those Nerve-Racking Battles of Business

HAVE your nerves protested at last against the long strain of man-to-man competition, conflict and anxiety? Has the slow, steady sapping of your nerve strength left you in a state of dangerous exhaustion? Your doctor will say, "You need a tonic" not a mere stimulant, but a real *reconstructive* help that will make good the over-draft on your system. When you are advised to take *the* food-tonic, Sanatogen -- and *when this advice is echoed by friends who* have actually *felt* the wonderful aid of this nourishing, *upbuilding* food-tonic--can you do better than follow such advice?

More than 19,000 practising physicians, over their own signatures, praise the restorative powers of Sanatogen Prominent men and women in every walk of life, after *personal experience*, tell enthusiastically how Sanatogen "brought them back", "lifted the strain of sleeplessness and indigestion", "gave them nerve energy and courage".

Should you hesitate to give yourself the benefit of this unequalled help? Is it not your duty to do so today?

Sanatogen is sold by good druggists everywhere, in three sizes from $1 00

Grand Prize, International Congress of Medicine, London, 1913

Sir Gilbert Parker, M P
the eminent novelist statesman, writes from London:
"Sanatogen is to my mind a true food tonic, feeding the nerves, increasing the energy and giving fresh vigor to the overworked body and mind"

Charles D. Sigsbee,
Rear Admiral, U S Navy, writes:
"After a thorough trial of Sanatogen I am convinced of its merits as a food and tonic Its beneficial effects are beyond doubt"

The Biggest of French Dirigibles

(Concluded from page 232.)

incased and decked over like all of the car, which shows also general stream-lines, and has a pretty, windowed observatory with a searchlight in its nose. A machine gun is to protrude through a gun port in the side—rather an antiquated practice. The engine room in the center contains auxiliary machinery—a ventilator for the ballonets, and dynamos for electric lighting and the wireless, of which the instruments are carried in the observatory in the nose. The Astra plant has also worked out an efficient system of swiveling propellers, to be installed in their next leviathan. This plan has given great satisfaction on a small scale in England, but will eventually become of vital necessity, as no force of men could handle a mammoth dirigible so efficiently and economically on the ground in landing and starting as 1,000 horse-power applied to a swiveled propeller. Theoretically it would take a handling crew of 2,000 men to equal it

Newest Way of Detecting Art Forgeries

(Concluded from page 237.)

first shows a microphotograph magnified some two and one half to three diameters of one of the heads in the well-known Watteau in the Edinburgh National Gallery The second is the same head from a very careful copy by an accomplished artist, which, except for the fact that it is newer and shows the absence of cracks, it is very difficult to distinguish by the eye from the original. This is clearly seen on comparing the photographs of the original and the copy But the moment that the microphotographs are compared the weakness and inferiority of the brushwork in the copy is at once revealed, and also the want of delicate modeling in the drawing of the face and the ear. The third photograph is from the well-known Pater in the Edinburgh collection, and is of great interest as showing distinct resemblances to Watteau's methods, while, at the same time, the work is facile and shallow and wanting in the rich complexity and subtlety of the work of the master.

The sixth photograph is from the head of a man in the Teniers (No. 817) in the National Gallery, London, and is an interesting revelation of the brushwork of this great artist. I may say that his brushwork is extraordinarily minute, it being difficult to understand how he had sufficiently fine brushes to put in some of these tiny strokes, which it must be remembered are shown here highly magnified and are therefore almost too fine for the eye to see in the original picture.

The next two photographs are examples of the brushwork of Velasquez, and illustrate the importance of seizing the work of the artist in a carelessly rapid painting mood One is taken from the tassel on the "Silver Portrait" of Philip in the National Gallery, London, and the other is taken from the tassel on the leg of "The Spanish Admiral" Certain authorities have suggested that "The Spanish Admiral" is not by the hand of Velasquez, but, while a larger number of photographs would be required for absolute proof, a comparison of the brushwork in these two examples goes a long way to prove that "The Spanish Admiral" is by the hand of the great master.

Examples of the application of this process might be multiplied indefinitely, but probably the accompanying photographs will be sufficient to illustrate the process. It must not be supposed, however, that it is sufficient to take one or two photographs of a picture in order to make a proper investigation. The picture ought to be carefully studied under the microscope with a view to examining for repainting, and identifying the pigments and mediums. Certain portions should then be selected as characteristic examples of brushwork, and these again compared very carefully with other pictures supposed to be by the same master, and the [illegible] of the investigation both by

LEGAL NOTICES

PATENTS

If you have an invention which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection Please send sketches or a model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of more than sixty years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand Book on Patents is sent free on request. This explains our methods, terms, etc, in regard to PATENTS, TRADE MARKS, FOREIGN PATENTS, etc.

All patents secured through us are described without cost to the patentee in the SCIENTIFIC AMERICAN

gether in coming to any final conclusion.

These methods do not in any way supersede the work of the art expert. His opinion on the authenticity of the picture remains as valuable and important as ever But they come in to assist him in his labors, to limit the problem that he has before him and to check by exact methods the conclusion at which he may have arrived; and in cases where art experts differ as to the origin of a picture, such methods go a long way to bringing the matter to a definite conclusion. As an example, I have been lately trying to decide who is the original painter of "The Old Grey Hunter" in the National Gallery, London, ascribed to Paul Potter, and the results obtained are at present before Dr Bredius, who first suggested that this picture was by Verbeecq. I am also making a further inquiry into who is the painter of the portrait of Elizabeth Bas in the collection at Amsterdam, Dr Bredius having suggested that it is probably by Bol, and not by Rembrandt

The Tunnel Under the English Channel

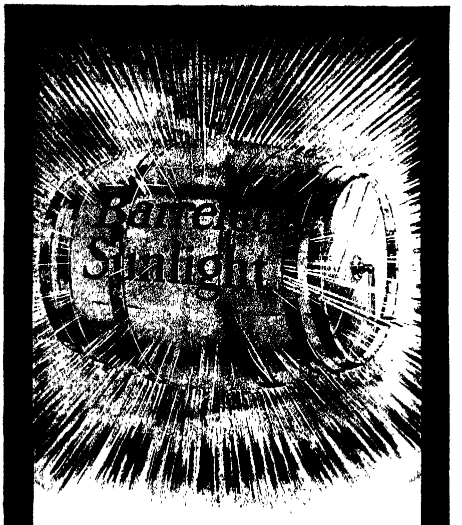
THE question of the tunnel under the English Channel is quite the order of the day in the two countries interested, and especially among persons who are occupied with engineering and economic questions Some interesting points about the proposed great work were set forth by M Monnier, professor at the Central School and chief engineer of the North Railway, in a recent conference on the subject. From an economic standpoint the construction of the tunnel will mean an enormous increase in passenger and all kinds of traffic, and will be a source of prosperity to England, France and other nations Capital will be easy to raise in both countries, and the cost is not expected to exceed $80,000,000. Technical difficulties appear to be less than for such mountain work as the Simplon tunnel and others What is intended for the channel enterprise is to work in the impermeable green chalk layer, and run two circular and parallel tunnels, with a railroad track in each tunnel Military preoccupations have now lost nearly all their importance in England in view of the good relations between the two countries, and it is considered that the enterprise cannot but add to ideas of peace and concord. The main obstacle to the realization of the project comes from the traditionalism which prevails in England, as it is held that the success and special qualities of the race largely come from the insular position of that country However, it is claimed on the other hand that such an idea does not fit into modern progress and that in the course of time it will lose its force, so that we may expect to see the project carried out at a not very distant date

Earthquakes and Changes of Latitude

AS long ago as 1903 Prof. Milne called attention to an apparent connection between displacements of the terrestrial poles and earthquakes. He found that in years when pole-displacements have been relatively large, world-shaking earthquakes have been numerous, and *vice versa.* Milne did not believe that the molar displacement represented by these earthquakes was sufficient to cause the polar change, but thought that both might result from a common cause. This subject has recently been investigated mathematically by Prof R. Spitaler, whose general conclusion is that the rapid axial displacement is the primary phenomenon and the earthquake secondary.

Large Lobsters

THE New York Aquarium has recently acquired a lobster weighing 21 pounds. Although this is a very unusual weight, specimens exceeding 30 pounds have been taken. According to the *American Museum Journal*, the largest known mounted specimens in the world are two in the American Museum of Natural History; one weighed when caught 34 pounds; the other, 31. These giants appear to be perfectly normal in every respect except size.



IF you could buy a barrel of anything which would increase the light in your factory 19 to 36 per cent, wouldn't you seriously consider its purchase?

That is a fanciful way of putting our proposition, but it is all fact, nevertheless *19 to 36 per cent actual increase in light* (depending on the present condition of your ceilings and walls) is what you will gain, if you paint the interior of your factory with

RICE'S
MILL WHITE

The only oil paint (without varnish)
giving a glossy, tile-like finish

Rice's Mill White will fill your factory with sunshine It will reflect every ray of your natural or artificial light down on your machinery and into the dark corners of your plant Its glossy surface will not absorb light or collect dirt, germs and odors like a flat paint It can be washed like tile

Rice's Mill White will not scale and require frequent renewals like a cold-water paint It will not "alligator" and crack under the jar of machinery like a varnish paint It flows easily under a 4 inch brush; two coats equal three of lead and oil *It stays white longer than any other gloss paint*

The Original Mill White

Rice's Mill White made a trade name of the words, "Mill White" None of its imitations has its elastic, permanent qualities No other paint manufacturer can use the Rice process *Rice's Mill White for ten years has proved itself unequalled for illuminating power, sanitary qualities and low ultimate cost*

Rice's Granolith
A tough and elastic permanent finish for concrete walls Becomes a part of the cement to which it is applied One coat sufficient, unless a gloss is desired Makes the best possible primer on inside concrete and brick for a second coat of Rice's Mill White Paint, giving a tile-like enamel finish at no more expense than lead and oil paint
For Concrete Surfaces

Rice's Mill White is sold direct from our factory, in barrels containing sufficient paint to cover 20,000 square feet, one coat. If you have that area of ceiling and wall space to cover,

Valuable Books

The Modern Gasoline Automobile
ITS CONSTRUCTION, OPERATION, MAINTENANCE AND REPAIR.
By VICTOR W PAGE. Octavo, 693 pages, over 400 illustrations and folding plates. Price, $2 50.

The most complete, practical and up-to-date work published on the gasoline automobile, for owners, operators, repairmen, salesmen and all others who are connected with the automobile industry in any capacity. It contains the latest and most reliable information on all phases of gasoline automobile construction, operation, maintenance and repair. It is clearly and concisely written by a recognized authority, familiar with every branch of the automobile industry, and is just as valuable as a reference and compendium of the latest automobile practice as it is desirable as a text book for teaching the beginner. It is not too technical for the layman nor too elementary for the more expert. Every part of the automobile, its equipment, accessories, tools, supplies, spare parts necessary, etc., has been fully discussed. It tells you just what to do and how and when to do it. Nothing has been omitted, no detail has been slighted. This work is superior to any treatise heretofore published and is right up to date and complete in every detail.

Scientific American Reference Book
EDITION OF 1914.
Compiled and Edited by ALBERT A HOPKINS and A RUSSELL BOND, 12mo, 597 pages, 1000 illustrations. Price, $1 50.

A handy, compact, reliable and up-to-date volume for every-day reference, containing a remarkable aggregate of facts, statistics and readable information along industrial, commercial, scientific and mechanical lines of interest to everyone. This volume is a revelation in the nature of facts and figures relating to population, manufactures, commerce, railroads, shipping, mining, agriculture, education, aviation, armies and navies of the world, Panama Canal, post office affairs, telephony, telegraphy and wireless telegraphy, patents and copyrights, chemistry, astronomy and time, meteorology, mechanics, weights and measures, and thousands of other subjects. It will prove invaluable on the desk of the business man as well as the library of the home. No expense or effort has been spared to make it interesting as well as authoritative.

Wireless Telegraphy and Telephony Simply Explained
By ALFRED P MORGAN. 12 mo., 154 pages, 156 illustrations. Price $1 00

A popular, practical and simply worded treatise embracing complete and detailed explanations of the theory and practice of modern radio apparatus and its present-day applications. The author has filled a long-felt want and has succeeded in furnishing a lucid, comprehensive treatise for the operator, both amateur and professional. A close study of its pages will enable one to master all the details of the wireless transmission of messages and to design and construct his own apparatus. Although based on scientific principles, no attempt has been made to give mathematical explanations. It is written so that it can readily be understood by men who are not technical and at the same time is sufficiently comprehensive and practical to be studied advantageously by the ambitious young engineer or experimenter.

Any of these books will be sent postpaid on receipt of advertised price

Notes and Queries

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12958) R. F. F. asks: 1. In the September 27th 1913, issue of the Scientific American appeared an interesting article on "An Electrolytic Rectifier for the Garage." I would like to ask a little information on this subject, and will appreciate your assistance. As I understand, a rectifier of this type is made possible by the fact that aluminium has the peculiar property of receiving an electric current, but preventing its passage from the plate's surface, when immersed in certain liquids. This being the case, then as I see it, when the H. T. winding is at any one instant, say—polarity, as shown, the L. T. will of course be as shown. This means that the current inside the L. T. winding is flowing in the direction as shown by the arrow. As this current cannot leave the aluminium plate on the right, it must pass down the center wire and into the side of the battery, and from the—side up through the left plate and so to the—side of the L. T. winding. On the reverse side of the cycle, the conditions would be the same, except that the current then would pass through the right plate. Is this reasoning correct? And, if not, will you kindly advise me where I am wrong, and give me the right idea? A. The electrolytic rectifier depends upon the fact that aluminium is very easily oxidized, and thus, when the current passes from the iron to the aluminium, that is, when the iron is plus to the aluminium, the negative oxygen readily goes to the aluminium to oxidize it. But when the aluminium is plus to the iron, the current is largely suppressed. The result is that a succession of impulses all in one direction flows out from the electrolytic cell, constituting a unidirectional current, that is, direct but not wholly continuous. You will find the theory well stated in our Supplement 1644, price, 10 cents. 2. I would also like to ask you what you think of the following scheme. The transformer is an auto transformer so connected that I can get about 15 volts or whatever is needed to force the 2 to 3 amperes D. C. through the battery. I would use a single-cell aluminium and iron plate of about the same dimensions as given in the Scientific American article. The action would be very similar to the mercury arc rectifier, the whole action being based on the fact that the current cannot leave the aluminium plate, but *will* pass to it. Of course, some little experimenting might be necessary to secure the right voltage connections and sizes of iron and aluminium plates before the proper charging rate was secured, but I do not see why this would not work. If you see where I have reasoned wrong, will you kindly advise me? A. It is not a practical arrangement to use a single cell as you propose, because only one half of each cycle is utilized, and in addition there is a slight leakage on the other half cycle, which opposes the direct current. With two cells, an efficiency of 60 to 65 per cent can be obtained. The article in our issue of September 27th, 1913, does not discuss the theory at all, but simply gives practical data, which should be closely followed. 3. Further, you have the transformer wound with a ratio of turns 800 to 240, which with 110 volts H. T. would give 33 volts L. T. As I understand, since but half the L. T. winding is used at a time, the secondary voltage really is about 15. Is this correct? What I am driving at is this. I have one or two small transformers which I have made, and was figuring on using one of them, with a secondary voltage of about 30, and using the middle tap. A. The secondary voltage will be as you have calculated, about 16.5, since one half the secondary winding is in use at once. Should you wish different voltage, you can use a different ratio of winding, and employ the method shown in Supplement No. 1644.

(12959) S. G. asks: There is an alloy of potassium and sodium which is liquid at the ordinary temperature like mercury (NaK$_2$). I should like you to inform me whether this alloy has any practical uses (excepting its use in high heat thermometers, where mercury boils at 360 deg. Cent.), and especially whether it can be kept exposed to the air for any length of time? A. We are not able to give any information regarding this particular alloy and its uses. Perhaps some of our readers can supply the information desired. It certainly cannot be exposed to the air for any time. It would oxidize immediately.

(12960) S. P. asks: 1. Will you please answer this question for me? If a tree falls out in the woods, and there is no ear in hearing distance, is there any noise? Please explain this for me. A. There are two definitions of the word "noise." One is that which we hear, and the other is the cause of hearing, the sound of the falling tree, in the case which you propose, a tree falling in a forest. The same effect is produced in the air, by the tree falling, whether there is anyone to hear the noise or not, but if there is no ear to hear, there will be no sensation of hearing, and in this sense of the word there will be no noise. If you use the word as meaning a sensation, then there is no noise where there is no ear. If you mean the physical motion which causes such a sensation, then there is a noise, whether there is an ear to hear it or not. 2. What is noise? A. A noise is a disagreeable sound, because the different components are not harmonious.

NEW BOOKS, ETC.

Tierwanderungen in der Urwelt. Von Wilhelm Boelsche. Stuttgart: Franckh'sche Verlagshandlung, 1913.

In this excellent little book Wilhelm Boelsche, one of the most popular writers on scientific subjects in Germany, discourses interestingly on those migrations in the animal kingdom which have played their part in the evolution of species. The book may be recommended for its simplicity to those German-reading Americans who take an interest in biology.

Telephon- und Signal-Anlagen. Ein Praktischer Leitfaden für die Errichtung Electrischer Fernmelde- (Schwachstrom-) Anlagen. Herausgegeben von Carl Beckmann. Berlin: Julius Springer, 1914. Mit 426 Abbildungen und Schaltungen und einer Zusammenstellung der gesetzlichen Bestimmungen für Fernmeldeanlagen.

A text book of the theory, construction and operation of telephones, with full descriptions of accessories and lay-outs. It is profusely illustrated and is a valuable book, either for study or for reference.

Mechanics for Builders. Part I. By Edward L. Bates and Frederick Charlesworth. New York: Longmans, Green & Co., 1913. 12mo.; 201 pp.; with diagrams. Price, $1 net.

Part I of the work in hand is designed to meet the requirements of students attending classes but one evening each week; used in this way, it constitutes a first-year course, which Part II continues as a second-year course. But the work may all be completed in a single year if the student can devote more time to the subject. The appeal of the work lies in its adaptation to its viewpoint—it keeps the builder and building requirements constantly in mind and aims to make the examples and exercises typical and practical.

Modern Seismology. By G. W. Walker, A.R.C.Sc., M.A., F.R.S. New York: Longmans, Green & Co., 1913. 8vo.; 94 pp.; with plates and diagrams. Price, $1.40 net.

This authoritative monograph on present-day seismology is limited to its consideration as a branch of physics. Incidentally, it is an appreciation of Milne and his work; for this we are grateful, since Milne's position as the father of modern seismology has received scant recognition. The first four chapters deal with seismometry—dynamical theory, sensitiveness, damping and registration, the various types of seismograph, their standardization and installation. The latter part of the work comes under seismogeophysics, and treats of the theory of a solid isotropic earth, the interpretation of seismograms, and the determination of epicenter and focus. An interesting chapter is that on "Seismic Effects other than Those Due to Earthquakes." The work concludes with a statistical consideration of the subject.

The Economics of Telegraphs and Telephones. By John Lee, M.A., Traffic Manager Post Office Telegraphs. London and New York: Sir Isaac Pitman & Sons, Ltd. 8vo., 86 pp. Price, 2s. 6d., net.

This very interesting review of telephone and telegraph activity in its relation to social and commercial conditions is written from an English standpoint, but American practice and development occupies much space in the comparisons. Our tariff systems are commended, and we are given full praise for the degree to which we have availed ourselves of these modes of communication. The industrial and social influences and trends of telegraph and telephone operations are authoritatively sketched, and the study furnishes lessons for the present as well as prophecies for the future. The author's conclusions indicate the advisability of government ownership. He states that this is the natural conclusion to which research has led him, and not the result of any original bias.

Heaton's Annual. The Commercial Handbook of Canada and Board of Trade Register. 1914. Toronto: Heaton's Agency. 12mo.; 590 pp.

The present issue of the Annual completes the first decade of its publication. The traveler, the business man, anyone at all interested in the commonwealth across the border, will find here a wealth of useful information relating to the industries and activities of the Dominion. Its governmental departments, its titled people, its postal and cable regulations, and its customs tariffs and rules are embodied in brief but adequate statements. Its financial information is full and authoritative. There is a list of Canadian attorneys, others of railways and steamship lines and a table gives the cost of travel. The shipper's guide is a feature of wide appeal, and its "local opportunities" presents invaluable information to those interested. There is also a list of Canadian publications, and a section of tables dealing with currency, discounts, income on stocks, wages and freight.

Grundlagen der Physik des Fluges. Von Dr. Raimund Nimführ. Mit 10 Figuren im Text. Wien: Druckerei- und Verlags-Aktiengesellschaft vorm. R. v. Waldheim, Jos. Eberle und Co. Leipzig: Otto Klemm, 1913.

Practice Letters for Beginners in Shorthand. By D. J. George. New York: Isaac Pitman & Sons, 1914. Price, 35 cents.

First Lessons in Isaac Pitman Shorthand. New York: Isaac Pitman & Sons, 1914. Price 10 cents.

Old Play

The MAZDA Lamp of today which gives three times as much light as carbon lamps It embodies the results of MAZDA Service to the manufacturers

TURN the button—flash! Many lifetimes' study of electricity is summed up for you in that quick and splendid radiance

Your forefathers had more trouble in getting the light of a single, dim candle Yet we take this modern miracle for granted—this cheerful light summoned by the fingers, that is so many times more helpful, so many times cheaper per candle power than the cheapest candles

Think of the ancient men conjuring the flame from the sapling, the pine knot, the grease from animal bodies, the oil of the earth. Think of the world's long struggle for more light and cheaper light, unguided in earlier days by an adequate knowledge or by any systematic method of reaching the goal that was sought

Think of the joy of the Dutch burgomaster von Guericke, more than two centuries ago, when he proved to scientists of his time that electricity had the power to give forth light Think of these isolated experimenters turning cranks to light-flashes by friction, and of their endless groping to capture that light

Think of Franklin (one hundred and sixty years ago this past summer) flushed with excitement on discovering that the electricity of the sky could be conducted by a kite string

Think of the tremendous obstacles overcome in the production of Edison's first carbon incandescent lamp Electrical science was now to settle itself to the systematic study of this vast problem which in earlier days had been left to slow, blind, accidental advance And manufacture had begun to feel the impetus of help communicated by organized research, experiment and selection

Think of that next big step—this time the use of filaments of *metal*, such as tantalum and tungsten

But obstacles were still to be overcome For example, the tungsten paste filament was fragile The first MAZDA lamp gave more light and cheaper light, yet left something still to be added—greater sturdiness fully to meet the strain of every-day-usage

Then the triumph of the *drawn wire* filament in the MAZDA Lamp of today—*three times as much light* as the old style carbon lamps, with the same amount of electric current and rugged enough in elements and construction to round out the full wonder of its practical efficiency

The plodding scientists had climbed a step higher in the great world-journey between the humble candle and the ideal light

Will they stop here?

Will that group of scientists in the Research Laboratories of the General Electric Company at Schenectady be satisfied with these selected methods of construction revealed by the lamp marked MAZDA? The mark MAZDA itself answers that question

MAZDA is the mark of a Service and it designates the great plan by which the MAZDA lamp *shall continue to mean* the highest achievement in incandescent lighting MAZDA service means that the Research Laboratories are not only assembling the results of their own incessant and exhaustive investigations, and those of their associates in the active developing and manufacturing centers at Cleveland and Harrison, but are keeping in close touch with great experimental lamp laboratories in Europe

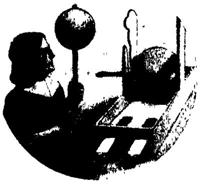
MAZDA Service means also the furnishing to the General Electric Company factories, and to the factories of other Companies entitled to receive this Service, every new fragment of knowledge, from whatever source derived, which shall be selected in the course of this service to the manufacturers for embodiment in the MAZDA lamp.

In other words, the mark MAZDA on a lamp means that this world-wide MAZDA Service has been received by the makers of that lamp

This is your assurance when you buy a MAZDA lamp—whether you buy it today, tomorrow, next month or at any future time—that you have the incandescent electric lamp that sums up the latest efforts of the broadest lamp service in the world

GENERAL ELECTRIC COMPANY

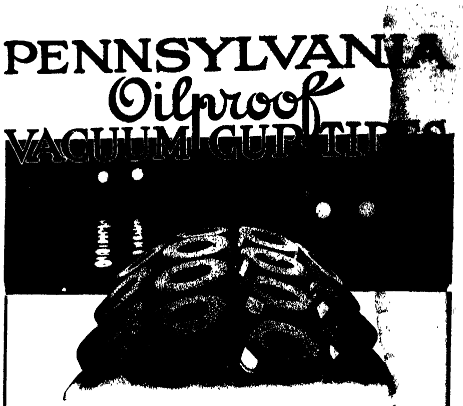
Franklin's early experiment in harnessing electricity



Von Guericke's electrical machine for producing electricity by friction

Even the shape of glass bulbs is a subject for constant experimentation

In one of the testing rooms of the Research Laboratories MAZDA Service involves unceasing tests and experiments with the aim that MAZDA shall always mean the furthest advance in metal filament lighting 4604



Question:

Do They Actually Prevent Skidding?

Answer:

For three years now we have sold these tires on our widely advertised guarantee that they will not skid on wet or greasy pavements, else returnable at full purchase price—

Never a challenge of this guarantee from a user

There's no limit to their skid-resistance—the heavier the slewing force, the stronger grows the multiple suction hold of the heavy walled Vacuum Cups The rolling tire lifts and releases the cups edgewise without drag on the forward speed

And what tires can match their service? Guaranteed for 4,500 actual miles—with many records of 12,000 to 15,000 on heavy cars and great excess mileage always the rule ***Absolutely oilproof.***

QUESTIONS AND ANSWERS

RELATING TO MODERN

AUTOMOBILE DESIGN, CONSTRUCTION, DRIVING AND REPAIR

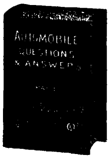
By VICTOR W. PAGÉ, M. E.

Author of "The Modern Gasoline Automobile," "The Modern Gas Tractor," Etc., Etc.

5¼x7½ Inches. 622 Pages. 329 Illustrations. 3 Folding Plates. Cloth.

PRICE, $1.50, *Postpaid*

A SELF-EDUCATOR ON AUTOMOBILING WITHOUT AN EQUAL



THIS practical treatise consists of a series of thirty-six lessons, covering with nearly 2000 questions and their answers—the automobile, its construction, operation and repair. The subject matter is absolutely correct and explained in simple language. If you can't answer all of the following questions, you need this work. The answers to these and nearly 2000 more are to be found in its pages.

Give the name of all important parts of an automobile and describe their functions? Describe action of latest types of kerosene carburetors? What is the difference between a "Double" ignition system and a "dual" ignition system? Name parts of an induction coil? How are valves timed? What is an electric motor starter and how does it work? What are advantages of worm drive gearing? Name all important types of ball and roller bearings? What is a "Three-quarter" floating axle? What is a two-speed axle? What is the Vulcan electric gear shift? Name the causes of lost power in automobiles? Describe all noises due to deranged mechanism and give causes? How can you adjust a carburetor by the color of the exhaust gases? What causes "popping" in the carburetor? What tools and supplies are needed to equip a car? How do you drive various makes of cars? What is a differential lock and where is it used? Name different systems of wire wheel construction, etc., etc.?

A valuable work written with special reference to the requirements of the non-technical reader desiring easily understood, explanatory matter relating to all branches of automobiling. The illustrations are distinctive, instructive and valuable, and everything is made clear to the novice by careful selection of parts and designs showing the latest domestic and foreign practice.

A popular work at a popular price. Answers every question you may ask relating to the modern automobile.

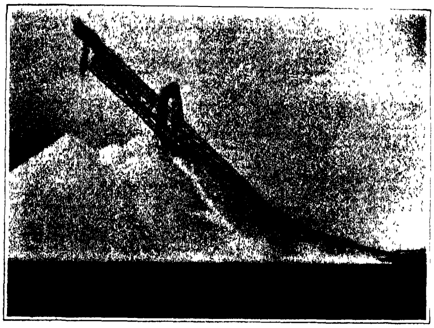

Fig. 2.—The dump growing rapidly under the conveyor.

Dumping Conveyor at the Brakpan Gold Mines

REMARKABLE as the highest, and perhaps the boldest construction of its kind in South Africa, is the sand conveyor at the Brakpan Mines of Johannesburg.

The refuse sand is drawn off from the cyanide tanks and shoveled into ropeway cars. These run down on an incline to the loading points, where they are stopped, and then proceed downward from the sand-treatment plant. At the extremity of this they pass out upon an inclined bridge, where they are clipped by means of a coupling apparatus to a traction rope in continuous motion, which hauls them up the bridge. On reaching the upper return sheave of the inclined bridge the cars discharge their contents automatically and return to the other side. The capacity of the plant amounts to about 180 tons of sand per hour. The single support of the inclined bridge is 166 feet high, the length of the bridge as first laid reached 200 feet in height, the bridge weighing 60 tons, and the lowest point of discharge for the cars being located at a height of 200 feet above the ground level.

Toward the close of the year 1909 the managers of the mines had under consideration a project to obviate the difficulties entailed by the employment of native laborers, and to handle the enormous quantities of material for which it is the usual custom on the Rand to employ belt conveyors. Although belt conveyors are well suited for handling material in bulk, and the total absence of frosts in the Rand district does away with the danger of handling moist sand, which is always present in our own climate, they, nevertheless, form a somewhat doubtful conveying agent for the material in question, because the finely ground quarts sand penetrates into the numerous axles and bushes, thus entailing great expense for repairs. Although the gold mines frequently employ belt conveyors for their other works, the above reasons decided them not to adopt this method for the removal of sand. They considered that closed boxes were, without doubt, the most satisfactory means of handling material which is detrimental to the mechanical conveying agent, because it remains undisturbed without being scattered or forming dust. An absolutely automatic traffic is equally possible on a ropeway as on a belt conveyor, and the dump can be readily extended, because it is only necessary to add further sections to the inclined bridge. At the beginning of the year 1910 the idea took definite shape, and it was decided that six cyanide tanks should first be served by the plant, and an additional four tanks connected at a later date. The suspension rails under the tanks were arranged horizontally for convenience in loading the cars, while the approach and departure were arranged at an incline. At the end of May, 1910, the contract was placed.

From a constructive point of view the nature of the material offered difficulties, as it has two natural angles of repose, one of 32 per cent for dry material, and the other of 42 per cent for moist sand The piling of the dumps by means of belt conveyors suffers greatly from these conditions because large quantities of steel structural work and open bridges are necessary to overcome these drawbacks. In the present instance it was, therefore, decided to erect only one lofty support, and to attach the inclined bridge to it, so that the dump could be gradually piled round the support, and under the inclined bridge, and in this way furnish ample support for the structural parts. This provided a basis for later extensions of the inclined bridge without providing supports, which is a characteristic of this type of bridge The angle of repose of the bridge was selected at 32 per cent, that is, for dry sand, because the carloads spread over the surface would rapidly dry

Definite data were available for the plant by July, 1910, whereby the daily capacity was assumed to be 1,000 tons, and the total length of the line 630 feet When working out the drawings, however, the plant was again extended, so that eight cyanide tanks instead of six were to be served The dispatch of the first mechanical parts was commenced at the beginning of August, and it was then that the first difficulties were met with. It was the intention of the mine management to have the steel work erected in South Africa, according to the drawings of the designers of this type of conveyor. When, however, the drawings arrived, and the contractor was able to appreciate the magnitude of the contract, he withdrew his tender, and negotiations lasted a month before a suitable firm could be found to undertake the erection of the steel work The bridge was put together on the ground, as the native laborers could not do the erection work up in the air The lowest cross-bars of the support were then loosened, and the slanting bridge drawn up with the aid of two 10-ton winches and pulley blocks The lower girders were then again set in place as shown in Fig 3, and the upper girders disengaged, in order to get the slanting bridge into its proper position This work was completed within a few days, and the bridge completely erected, as shown in Fig 1 The mechanical parts were speedily put on, and the conveyor was put into service at once

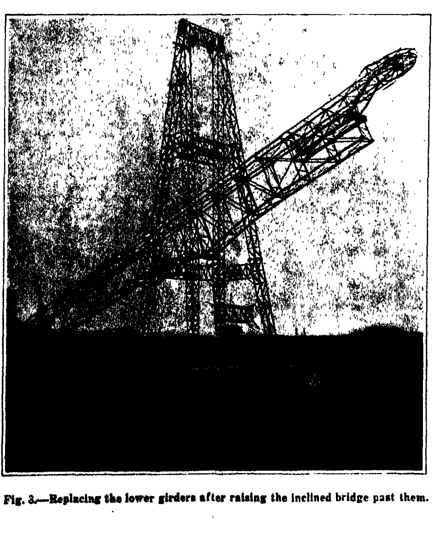

Fig. 3.—Replacing the lower girders after raising the inclined bridge past them.

As the dump gradually grew, the sand began to press against the supports, and it was, therefore, necessary (see Fig 2) now and again, to move the detent for tipping the cars on the slanting bridge, so that dumping could be effected evenly round the supports. The first extension of the bridge was ordered in January, 1913, as the dump had already reached a height of 200 feet at this point

The wire ropeway cars are equipped with an automatic coupling apparatus, which is actuated by the dead weight of the car It gives an absolutely safe and reliable clip to the rope on the heavy gradient of 32 degrees, besides offering the great advantage that it couples traction ropes of varying diameters with equal safety, so that no adjustment of the apparatus is necessary, even when in course of time the traction rope stretches somewhat, and its diameter becomes reduced The ropeway runs with an average power consumption of 60 to 90 horse-power

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

The Kodak Film Decision

THE decision recently handed down by the United States Court of Appeals, and printed on another page of this issue, upholding the Goodwin patent for the well known and widely used photographic film, contains one of the severest judicial arraignments of our patent system ever penned. It ought to be read by every congressman, by every inventor, by every manufacturer who makes patented goods—read because the daily press, scenting here the story of David and Goliath in a new form, has conveyed the impression that a struggling but obstinate clergyman was hounded by a great corporation with the sensational result that he came off the victor. We fear that the public will lose sight of the fact that a corporation has its rights as well as a poor inventor, and that the Eastman Company was entirely justified in exhausting every legal effort to evade a patent which it considered invalid.

Not the fact that a poor clergyman ultimately succeeded in beating a wealthy corporation (but with very powerful support, be it mentioned in passing) is to be taken to heart, but the shocking conditions which have rendered it possible to continue a dispute over the validity of a patent for a quarter of a century.

Eleven years and four months elapsed before the patent was finally granted. It had to run the full gamut of motions, counter-motions and appeals that make a patent interference a sore trial. And then, ten years and eight months elapsed after an infringement suit was brought before a United States District Court sustained five claims.

Apart from these delays, the history of the application in the Patent Office reflects no credit upon the officials. Five different examiners rejected the application during its eleven years' pendency in the Patent Office. No wonder the Court remarked: "Surely an extraordinary and deplorable condition of affairs!" No wonder, too, that the Court observes: "Most of the complications in the case would have been avoided had the Goodwin patent gone to issue in due course, as it should have done. The long delays and the contradictory rulings of the Patent Office would have discouraged an inventor who had not supreme faith in the justice of his cause."

The manner of conducting infringement suits has happily been vastly improved since the Supreme Court of the United States has laid down new rules. But the Patent Office cannot thus reform itself. Only congressional legislation can simplify the procedure in the Patent Office so that an inventor's vitality and finances may not be sapped by the interference incubus and so that a patent, which on its very face relates to novel subject matter, may be speedily granted. The SCIENTIFIC AMERICAN and other members of the technical press have for years insisted upon a more adequate protection of intellectual property. Latterly the magazines and the newspapers have taken up the fight. Perhaps this increasing hue and cry may at last be heard by our legislators.

The Washington-Paris Longitude Campaign

TO obtain the difference of longitude between two places on the earth's surface it is necessary to obtain their local times by star observations, and to effect an exchange of signals by means of which these times may be compared. The difference of the local times, at the epoch of comparison, is the required longitude difference. Among the many applications of wireless telegraphy to scientific purposes, the providing of a means for furnishing such signals in longitude operations is not the least. Particularly is this of value *to geographers and explorers of unknown lands*, and in other regions where the ordinary telegraph wire has not yet penetrated. During the past decade longitude determinations with the aid of radio signals have been effected in various parts of Europe, in Japan, and by the American Navy.

Transatlantic longitudes have hitherto depended on signals communicated over the cable; but experiments last spring having demonstrated the feasibility and advantages of wireless telegraphy, preparations were begun and plans laid for a determination of the longitude difference between Washington and Paris. This longitude campaign, at length opened in October, is now drawing to a close. Engaged in the operations are both Americans and Frenchmen, working separately and independently, each in co-operation with fellow countrymen on the other side of the ocean. There are thus four parties, two at Washington and two at Paris, each composed of astronomers and wireless experts, the former to make stellar observations, the latter to detect and note the radio signals. Synchronized by the standard clocks of the respective observatories, these signals are sent out, on the American side, from the powerful naval wireless station at Arlington, Virginia; and on the French, from the Eiffel Tower, Paris. Detected both by ear and by a sensitive photographic apparatus invented by the French, they are made use of not only for longitude, but also, through a knowledge of the distance separating Paris from Washington, for calculating the speed of propagation of the Hertzian waves. It may be added that similar experiments in other longitude campaigns have demonstrated this speed to be substantially that of light.

The longitude instruments employed are of the highest type known to astronomers, designed especially to eliminate, as far as possible, instrumental and personal systematic error. To guard against the possibility, nevertheless, of small residual personal equation influencing the results, the parties at Washington and at Paris exchanged places about the beginning of the year, carrying their instruments with them. At the time of this interruption, after a period of some three months, but six or seven favorable nights' work had been obtained. As a favorable night calls for clear observing weather both at Paris and at Washington, as well as conditions of the ether such as will permit satisfactory transmission of wireless waves across the ocean, it will be readily understood why it was planned to extend the campaign over a period as long as five or six months.

One advantage of radio over other methods of signal transmission is that anyone, with small receiving apparatus fitted up at slight expense, can detect the signals. The opportunity has accordingly been seized by a number of observatories on this side of the Atlantic to receive and record these signals, and in conjunction with astronomic observations, to obtain simultaneously their longitude differences from Washington. Longitude operations of a higher order of precision will doubtless, in time, be extended across the continent, and ultimately around the world. Frequent redeterminations are also proposed for the purpose of discovering possible creepings of the earth's crust.

The longitudes determined in the last century by cable differed from those previously obtained through more primitive methods by a second and a half of time. It will be interesting to learn how they agree with the wireless results, and how concordant will be the French with the American values. Longitude by wireless, after all, is still in the experimental stage. Publication of the methods employed and results obtained will be awaited by men of science with deep interest.

An Unsinkable Ship

THE term "unsinkable" as applied to ocean-going ships is strictly relative; and as so used, it means a ship which is unsinkable by any of the conceivable accidents of the sea which might overtake her. Such a ship would act as her own lifeboat, and were it not for the risk of fire, might dispense with the long lines of boats which crowd the top deck of the modern liner. The accident which sank the "Titanic" was of such a severe and unprecedented character that its recurrence, in the exact manner and with the same extent of injury, though conceivably possible, is certainly not likely. Nevertheless, since such an accident did happen, common prudence demands that the modern liner, to which is intrusted the lives of some five thousand people, shall be so constructed internally as to be proof against even such a terrific injury as that which sank the "Titanic."

At the time of that disaster, we were unsparing in our criticism of the construction of the ship, and therefore it gives us great pleasure to note that in their latest vessel, the "Britannic," recently launched, the White Star Company has so greatly improved the safety elements in the way of bulkheads and inner skins and watertight decks, that the ship could undoubtedly pass through such a severe ordeal as happened to the "Titanic" and yet remain afloat. Furthermore it is to the credit of the company that they have considerably exceeded the provisions for safety embodied in the report of the International Conference on Safety at Sea which sat in London last winter.

The "Britannic," which is 900 feet in length and of over 53,000 tons displacement at low draught, is provided with a double bottom over five feet deep, which is increased to over six feet throughout the machinery space. This bottom is divided by the transverse frames and by longitudinals into a vast number of watertight cellular compartments. Furthermore, we are pleased to note that the suggestion which the SCIENTIFIC AMERICAN made at the time has been followed in carrying the inner floor of the double bottom up the sides of the vessel to a height of several feet above the load-water line, thus providing throughout the boiler and engine room spaces a complete inner skin. The space between the outer and inner skin is thoroughly subdivided by the ship's frames and by a series of longitudinal girders.

Equally important as a safeguard is the fact that the main transverse bulkheads have been carried up, all of them at least one deck higher, and many of them two or three decks higher than they were in the "Titanic." There are sixteen of these bulkheads, five of which extend to a height of over forty feet above the deepest load line, while all the others are [illegible] to a height of over 21 feet above the water line. [illegible]ticular attention has been given to the design of these bulkheads, which have been specially stiffened [illegible] stand the maximum water pressure that can co[illegible] them, due to the deepest possible submersion of th[illegible] in case of injury. Forward and aft of the boil[illegible] machinery spaces, watertight steel decks, or "fla[illegible] they are called, have been worked in at or belo[illegible] water line; and this means that in the event of [illegible] a rupture of the skin as happened in the "Titanic," [illegible] water would be confined below these decks.

Another special safety provision is found in the unusual power of the Marconi apparatus on the "Britannic," which will have a transmitting radius of about 2,000 miles. An emergency power station has been built on a deck far above the water line to supply current for various purposes in case of accident to the main power station.

Excellent also and very original is the means provided for launching the lifeboats of which the ship carries forty-eight, two of which are fitted with powerful motors. The lifeboats are in four separate groups handled by a new type of davit which is practically a pair of powerful shear legs. These are so long that they will swing inward to the center of the ship, and outward so far that the boats may be lowered safely at any possible angle of heel of the ship.

George Westinghouse

THOSE who were privileged to know the late George Westinghouse will always remember that the thought of the vast benefits his inventions were conferring upon mankind was to him at all times *a source of deep satisfaction*. To mention Westinghouse is to think of the airbrake, which may safely be described as the greatest of all contributions to the safety of railroad travel. It was characteristic of the man that, great as was the early success of the airbrake, Westinghouse was ever industriously applying himself to its improvement; only recently we recorded a development of this brake as important, perhaps, as any produced since its inception. Equal in importance to his work on the airbrake was his influence in introducing and developing the alternating current system for electric light and power. With the patience, energy, and indomitable courage which marked the man, he purchased the original patents, developed them, introduced the system and made it thoroughly practical in this country. Safety in railroading is indebted to him also for the pneumatic-electric system of automatic signaling. Broad-minded and keen in his outlook, he was quick to recognize and purchase foreign patents of value and introduce them into this country, as witness the Parsons steam turbine and its widespread commercial development under his hand. His latest and most notable work was the invention and development of a practical, mechanical reduction-gear, for transmitting large powers, which is to be used in two new battleships and a repair ship of the United States Navy. Mr. Westinghouse's death occurred March 12th, in this city, in his sixty-eighth year. He won many distinguished honors abroad, receiving the Legion of Honor from France, the Order of the Iron Crown from Italy, and a decoration from King Leopold. He was awarded also the John Fritz Medal, bestowed by the leading engineering societies of the United States. The Royal Technical High School of Berlin gave him the degree of doctor of engineering. As showing the wide range of his activities, it may be mentioned that there are now between thirty-five and forty Westinghouse companies in Europe and America, capitalized at $200,000,000, and employing about fifty thousand persons.

Electricity

Longest Submarine Telephone Cable.—The telephone cable which is to connect Aldeburgh, England, with Walcheren, Netherlands, is to be 79 nautical miles in length, making it the longest submarine telephone cable in the world. It will furnish telephone communication between London and Berlin. The cable is to be of the four-core Pupin loaded type.

Linking Germany With Her Colonies.—The German government is negotiating with Holland to obtain permission to erect a wireless station on the island of Sumatra (Dutch West Indies). Such a station would, on the one side, be able to communicate with German East Africa, and, on the other, with the Caroline Islands. If this plan succeeds, all the German colonies would be able to communicate with Berlin without being obliged to make use of any cable. This would alleviate one of Germany's greatest grievances—that in communication with its colonies it is now so dependent upon Great Britain, which controls most cables.

Recent Telephone Statistics.—According to a preliminary report given out by the Director of the United States Bureau of the Census, 20,248,326 miles of telephone line were in use in the United States during the year 1912. This represented an increase of 313.2 per cent during the decade. In 1912 the Bell system controlled 74.7 per cent of the wires and 58.3 per cent of the telephones. The estimated number of messages or talks for the year was 13,735,658,245. This figure does not include messages for the 1,402,840 telephones of small companies which had an income of less than $5,000 during the year. The messages reported by the Bell system include only completed calls, while those reported by other companies may include some "line busy" or "do not answer" calls.

Death of John Gott.—Mr. John Gott, a pioneer of submarine telegraphy, died at Brighton, England, on March 8th, at the age of 75. He entered the telegraph service in 1852. From 1855 to 1864 he assisted in cable laying in the Mediterranean and the following year he was one of the crew of the "Great Eastern" on her first attempt to lay a transatlantic cable. He became the superintendent of the French Atlantic Cable Company's station at St. Pierre, Miquelon, in 1869, and has been chief electrician of the Commercial Cable Company since its inception. However, his greatest achievement came in the last year of his life when he developed a system of cable telegraphy, employing a Morse sender and receiver, thus doing away with the syphon recorder and making it possible to relay the messages from and to land lines. Nine months ago a message was sent through from San Francisco to London without retransmission. A description of the system was published in the SCIENTIFIC AMERICAN of November 22nd, 1913.

New Electric Locomotive.—Among recent European electric locomotives we may mention the one built for the Rhätische railroad system. It is being used on the St. Moritz-Schuls line which has a branch from Samaden to Pontresina. The line is narrow gage and is supplied by single-phase current at 10,000 volts and 16 2/3 frequency, the locomotive being required to draw a train of 20 tons maximum. The locomotive carries two electric motors of 350 horse-power each. A single countershaft takes the power from both the motors by gearing, and this shaft serves to run all four driving wheels on a side. Between the third and fourth locomotive axle is mounted a false axle which receives power from the countershaft by means of a crank, and this axle serves to operate the four locomotive axles. The present locomotive runs very well in actual service, and during the first three months it is stated to have covered 8,500 miles. Current comes from an overhead trolley wire by two pantagraph trolleys, the locomotive being of the square or box-built type.

New Telephone for the Deaf.—One of the newest telephone devices for the use of the deaf is the German "phonophor," consisting of a telephone transmitter worn on the person or placed upon a table, and a small telephone held to the ear. The most novel form of the device is the one intended to give a great reinforcement to the sound by the use of powerful telephones, and here it is made up for ladies' use in the shape of a small leather handbag of familiar shape. Lifting up a flap uncovers a pair of microphone transmitters, and the bag is simply placed on a table, a store counter or the like, while a small hand telephone is held to the ear, or the latter device can be used as a head clamp by a little adjustment. The bottom of the bag is flat so as to stand upright, and it can not only contain the battery and the ear device, but also leaves room for other objects. Sounds are made still louder by a more powerful type intended for men's use, and it has the appearance of a kodak box with four microphones inside, whose openings are flush with the surface and covered with perforated plates. The box is placed on the table and a light headpiece holds a telephone to the ear.

Science

Standard Time in German East Africa.—Uniform time of the meridian 37 deg. 30 min. east was officially adopted in German East Africa on October 1st, 1913.

An International Congress of Ethnology and Ethnography will meet at Neuchatel, Switzerland, June 1st to 5th, 1914.

An Important Event in Asian Geography was the recent linking up of the survey of India with the Russian triangulation in the Pamirs, a task which has involved five years of labor. Some of the British stations were at altitudes ranging from 18,000 to 19,000 feet above sea-level.

Sir Isaac Newton's House, No. 35 St. Martin's Street, Leicester Square, London, is about to be pulled down, as it is in so ruinous a condition that any attempt to preserve it would be hopeless. This house is not only historic on account of the great philosopher's residence here from 1720 to 1725, but also as the home subsequently of Dr. Burney, the composer, and his daughter Fanny, who wrote her first novel, "Evelina," here.

The Katmai Dust Cloud, which caused a general haziness of the atmosphere over much of the northern hemisphere, reaching a marked maximum in August, 1912, appears to have now practically disappeared. As pointed out by Prof. Kimball, the duration of this cloud was somewhat less than that due to the eruptions of 1902–03, which lasted two years, and markedly less than that of the dust ejected by the great Krakatoa eruption of 1883.

Explorers Killed by Cannibals.—It is reported that a forester named Deininger, who was attached to the Woods and Forests Service of German East Africa, but had been sent to New Guinea to help organize the forest service there, has been murdered by cannibals in the island of New Mecklenburg, where he was collecting specimens of valuable woods. Another German scientist and fourteen native companions are said to have shared his fate.

A New Volcanic Island has appeared in the Bonin group, three miles east by south of Iwojima Island. It is five miles in circumference and attains a height of 1,000 feet. The appearance of this island is especially interesting for the reason that the other Bonin Islands, although of volcanic origin, are believed to date back to Eocene times. They contain no hot springs, and are not subject to earthquakes.

New Atmospheric Gases.—In a paper read before the British Association meeting at Birmingham, F. W. Aston reported investigations which indicate that neon, one of the rare gases of the atmosphere, is really a mixture of two gases, which are identical in all their properties except atomic weight. That of the heavier is 22.1, and of the lighter 19.9. Ordinary neon appears to contain about 12.5 per cent of the heavier gas. The spectra of the two gases appear to be identical.

Yet Another Antarctic Expedition is in prospect, according to plans briefly outlined in *Petermanns Mitteilungen.* This will consist of an attempt to trace the entire outline of the Antarctic coast, and will be undertaken by Commander Evans, who succeeded Scott in command of the last British expedition. His plan is to circumnavigate the continent, keeping as close to the shore as the ice will permit, and making numerous landings. The geographical importance of such an undertaking equals or exceeds that of Shackleton's proposed trans-Antarctic journey.

World-shaking Volcanic Earthquakes.—One of the most interesting facts in connection with the recent eruption of Sakurajima, in Japan, is that earthquake shocks were strongly registered in Europe at the time of the shocks which attended the eruption, and caused so much damage in the neighboring city of Kagoshima. According to C. Davison, who discusses the subject in *Nature*, this is the first time that a volcanic earthquake has been recorded across an entire continent since the horizontal pendulum was adapted for seismographic purposes. Volcanic earthquakes as a rule are decidedly local, indicating that the seat of the disturbance is at a very moderate depth in the earth.

Periodical Medical Examinations for Everybody, as a means of detecting and checking disease in its earliest stages, were earnestly advocated by Dr. Victor C. Vaughan in an address on the subject of preventive medicine before the seventh annual meeting of the Association of Presidents of Life Insurance Companies. Looking into the future, the speaker told of the time when "everybody goes to a physician twice a year and undergoes a thorough examination. The result of this examination is stated in a permanent record, and no two consecutive examinations are made by the same physician, in order that a condition overlooked by one may be detected by another. Cases of doubt, or in which there is difference of opinion, are referred to special boards." Dr Vaughan indorsed the proposal that the insurance companies offer their policy holders free medical re-examination at stated intervals; a plan that would probably benefit the companies financially through the increased longevity of the insured.

Inventions

Typewriter Eraser Operated by a Key.—In patent No. 1,083,466 Harry I. Seddon of Portland, Ore., provides an erasing means for a typewriter in which an erasing head is yieldingly pivoted on a bar and the latter is connected to a key lever so that the key lever may be moved to operate the eraser.

Uniformly Curved Trifocal Lens.—Henry Boldo of New York, assignor to the Meyrowitz Manufacturing Company, has patented a trifocal lens in which two minor lenses are seated respectively in the two faces of a major lens, both of the faces of the completed lens being of uniform curvature throughout.

Rimless and Removable Eye-glass Lenses.—Rimless eye-glasses, in which the lenses are detachably mounted in a wire holder, are shown in patent No. 1,084,262 to Robert James Fleming and Thomas Alfred Robinson of London, England. It is claimed that the lenses are securely held and may be easily fitted and removed by the wearer.

A Hollow Metallic Propeller.—Pierre Jacomy, Asnieres, France, in patent No. 1,082,750 presents a light hollow metallic propeller which is made of a single piece of metal in the form of a weldless tube with its edges or ends of a decreasing cross section and the ends formed into helical blades, openings at the center receiving a sleeve.

A Novel Nozzle for Cotton Pickers.—Emil Gathmann of Baltimore, Md., has provided a nozzle for pneumatically operating cotton pickers which flares outwardly funnel shape and has on its inner side a spiral-toothed rib with a plurality of connected convolutions designed to engage the cotton, dislodge from the boll and direct it inward into the machine.

An Improved Moving Picture Screen.—A patent No. 1,082,123 was issued to Samuel H. Jones, of Altus, Okla., for a process of producing a moving picture screen in which an oil-cloth base is subjected to a softening oil after which a coating of jap-a-lac and turpentine and after that has partially dried a metallic powder is rubbed in until a velvety sheen is produced. It is claimed that the pictures thrown on such screen will be more distinctly shown and brought out more in detail and that the screen can be used in daytime.

A Process of Canning Asparagus.—Patent No. 1,083,311 to George W. Weber of St. Paul, Minn., assignor to American Can Company, of New York, presents a process of canning asparagus and other food products in which the asparagus or the like is placed in a sheet-metal container and the container is subsequently reduced or compressed midway between its ends to grip and hold the food product and prevent it from movement within the container, thus preventing any breaking up that might result from its moving about in the can.

Automatic Lock Release for Express Safes.—In patent No. 1,083,101 John Holeck and David Schwartz of Milwaukee, Wis., provide an express safe for cars in which there is an inner stationary receptacle, a stationary outer casing and an interposed rotary shell which is driven from an axle of a railway car and lock mechanism for the doors of the shell and casings are provided. The lock mechanism is entirely within the safe and prior to closing the safe the operator sets the pointer to correspond to the number of miles to the next station or point determined upon where the automatic unlocking takes place.

A Crown Seal Closure that Will "Pop."—In patent No. 1,082,696 to Arthur W. Hicks, administrator of John Augustus, deceased, is shown a bottle closure having a metal cap secured over the mouth of the bottle and a lining in the cap which has an impervious adhesive face which adheres hermetically to the bottle mouth while the lining is unattached to the cap so that in removing the cap from the bottle the top is separate from the lining and the lining will be blown from the bottle mouth with an explosive sound by the pressure of gas in the bottle.

Rescuing From Submarine Boats in European Navies.—The subject of saving lives of men on submarine boats, the mechanism of which has been deranged, has been attracting considerable interest throughout the world recently. The importance of this subject was brought out by a recent disaster in the British Navy. Several European navies have installed apparatus on their submarine boats for renewing oxygen and absorbing the products of respiration from the men on the boat for a period of seventy-two hours, during which time it is usually possible to effect a rescue which otherwise would be prevented by the men suffocating. Another popular method is to locate in the boat a number of little machines designed to shut off the respiratory organs of the wearer from the water, and permit him to breathe fresh air supplied by a special device until he can rise to the surface of the water, after which the device may be thrown away, the balance of the apparatus serving as an ordinary life preserver until rescue can be effected. These little machines have also been used for rescue work at bathing beaches very successfully.

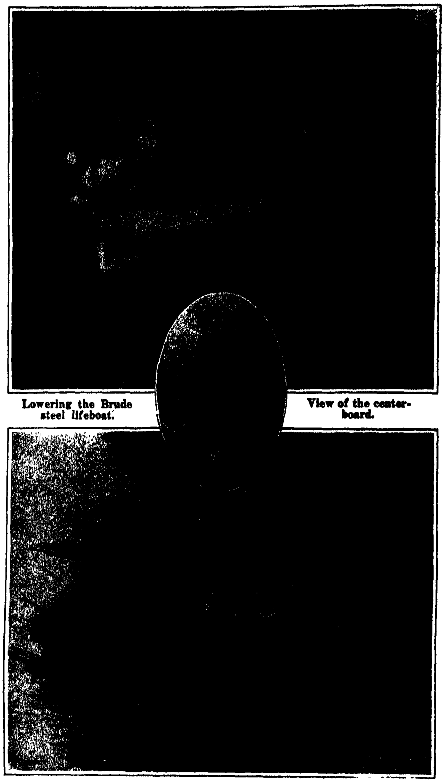
A Real Lifeboat

By Robert G. Skerrett

THEORETICALLY, at least, a lifeboat is deserving of that name when it measures up to the requirements imposed by the exigencies of the service for which it is designed. As a broad proposition, lifeboats upon seagoing craft are provided in order that the passengers and crew may leave a stricken vessel, or that they may be put overboard from a succoring craft for the purpose of rescuing others in distress. To do this, the lifeboat should be of such an order that it could be gotten into the water with haste and not impose too much skilful handling to accomplish this effectively. Next, when afloat, it should be capable of carrying and protecting the while those within it. The boat should be so constructed that it would live in a stormy sea, and while making harbor or awaiting the coming of aid, be able to keep alive those that it has taken from the abandoned ship. How far does the average lifeboat live up in fact to this theoretical standard?

Thirty-one men—all hardened and experienced seamen—tried to get away from the oil-tanker "Oklahoma" during a recent frigid storm. One boat capsized after hitting the water, and six out of the eleven in her were drowned. The five others were rescued through the courage of a boat's crew from another craft. The second boat got away with twenty aboard, but seventeen of these had disappeared when relief came. Two of the three remaining were dead, and the other died without regaining consciousness All perished of exposure.

On some sixty vessels flying the flags of Norway and the United States, there is installed a type of lifeboat which uniquely meets the ideal requirements. The boat is the invention of Capt. Ole Brude, an experienced mariner. The Brude boat is built of steel with a deep double bottom in which can be carried both drinking water and water ballast; it is equipped with a lowering centerboard to facilitate sailing; and is globular in shape by which it is possible *to protect the passengers from* the sea and the weather Because of its *form, method of construction, and heavy* wooden guard, the boat is exceptionally strong. It is *non-capsizable*; virtually non-sinkable; and, with persons inside, has been dropped without harm from a height of nearly forty feet. When the two circular hatches are closed, the boat, *pro tem*, is as snug as a submarine. A boat of this type is in fact a lifeboat and liferaft combined, and has an inside seating capacity for thirty persons, but can carry and support forty-five more outside. A boat of this type crossed the Atlantic in mid-winter a few years ago under sail, and weathered several severe gales on the journey. The four men aboard of her suffered no inconvenience despite the bitter weather It was the successful conclusion of this convincing practical test that gave the Brude boat its first recognition. This is the character of lifeboat that should be generally provided for all ocean-going steamers, as it is a lifeboat in the fullest sense of the term.



Lowering the Brude steel lifeboat.

The Homing Instinct in Crabs is illustrated in some cases recently reported from England. Several crabs from Yorkshire, liberated at Skegness, in Lincolnshire, walked home again A most remarkable case was that of a pair of crabs, male and female, which were taken in the same trap off the Yorkshire coast They were carried to Lincolnshire, marked, and returned to the sea at different places along the coast. In the course of time the same pair, having found each other in the sea, were captured together a second time in a trap at their original home in Yorkshire.

Cinematographs of the Aurora, taken by Carl Störmer at Bossekop, Lapland, are reproduced in a recent number of the *Comptes rendus* Most of his attempts to obtain such pictures were unsuccessful, on account of the feeble luminosity of the phenomenon, but on three occasions, during particularly bright auroras, he secured excellent results. Each image was given an exposure of from one half to one second.

Enlarging and Reducing Phonograph Records

By R. Arapu

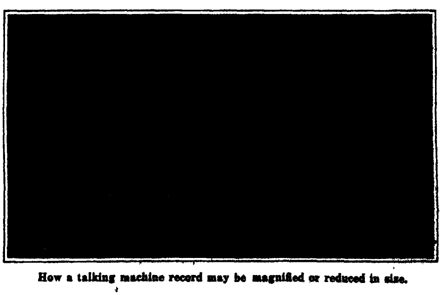
THE ingenious method of enlarging and reducing phonograph records, which is here described, was invented by M. Georges LeRoy, director of the chemical laboratories of the city of Rouen

Phonograph records, i e., the traces made on wax disks or cylinders by the needle of a recording phonograph, can be enlarged or reduced by the following physico-chemical process, without the aid of the pantograph, by which such reproductions have hitherto been made exclusively. In the first place it should be observed that the new process is superior to the pantographic method because it excludes the employment of levers and other mechanical organs, which inevitably affect the record by means of their own vibrations and reactions. On the other hand, the record may be improved by employing the new process. In current practice, the primary wax record is made by means of sounds of exaggerated loudness in order to produce a strong impression, and injurious secondary vibrations are thus evoked and recorded. By the new process a record made with tones of moderate intensity, free from disturbing secondary vibrations, can be enlarged until it produces tones as loud as may be desired. Conversely, a record made with loud tones can be reduced, and thereby softened, in addition to being compressed into smaller compass.

Principle of the Process.—The enlargement is effected by the dilatation of molds of the primary record, made of material which is greatly dilated by prolonged immersion in appropriate solutions; for example, gelatine immersed in aqueous solutions, or vulcanized rubber immersed in carbon disulphide. Conversely, the reduction is effected by the contraction produced in similar molds by appropriate treatment, as by the dessication of a mold composed of highly hydrated gelatine.

Technique of the Process.—From the primary wax record a copy is made in copper by galvanoplasty. For enlargement a mold of this copper record is made in a concentrated solution of gelatine, containing 30 to 50 per cent of dry gelatine. The gelatine mold is immersed in cold or tepid water, pure or containing substances that promote the expansion of the gelatine. When the mold has attained the desired size it is made insoluble by immersion in a solution of formol, and is then molded in wax or plaster. From the wax or plaster mold is made a galvanoplastic copper matrix, or master record, with which the working records are stamped. The diameter of the soft gelatine disk can be tripled by immersion, and the enlargement can be increased indefinitely by repeating the process on gelatine copies of the enlarged plaster or copper matrices.

For reduction the copper plate made from the primary wax record is used to produce a copy in weak gelatine, containing 10 to 25 per cent of dry gelatine, which is dehydrated by immersion in dilute alcohol, a solution of sodium sulphate or of Rochelle salt, by exposure to a current of dry air, or by the action of a vacuum desiccator. The gelatine record, thus contracted and reduced, is copied successively in wax or plaster and in copper, in the manner described above. The diameter of the gelatine disk can be contracted to 60 per cent of its original value, and the reduction can be continued indefinitely by contracting gelatine disks made from the reduced copper plates. In the accompanying photograph No. 2 represents an original record of 120 millimeters diameters, No. 1 a reduction to 80 millimeters, No. 3 an enlargement to 190 millimeters, and No. 4 a second enlargement to 340 millimeters.



How a talking machine record may be magnified or reduced in size.

1. Shows a reduction to 80 millimeters diameter. 2. The original record of 120 millimeters 3. An enlargement to 190 millimeters. 4. A second enlargement to 340 millimeters

---

Protective Spectacles for Glassworkers.—At a recent meeting of the Royal Society Sir William Crookes described some experiments on which he has been engaged to produce a kind of glass for use in spectacles which will cut off the extreme heat rays that are so injurious to the eyes of glassworkers in causing cataract, without obscuring too much light or materially affecting the color of objects seen through the glass. He sought also to cut off the ultra-violet rays. Although the ideal glass, which would transmit all the colors of the spectrum, but cut off the invisible rays at each end, has not yet been found, he has produced spectacles which transmit less than 10 per cent of the heat rays, and none of the ultra-violet, and are sufficiently free from color for practical use. He doubts whether absolute freedom from color is desirable. After experimenting with a great number of elements he found that combinations of two or more of the following were likely to come nearest to the desired result; Cerium, chromium, cobalt, copper, iron, lead, manganese, neodymium, nickel, praseodymium, and uranium.

The Rise in Prices and the Increased Cost of Living

Changes in Leading Manufacturing Countries of the World During the Period 1900-1912

By John B. C. Kershaw, Fellow of the Royal Statistical Society, London

THE industrial unrest, which is such a marked feature in all the civilized countries of the world at the present time, has been ascribed to many causes. In an article published in April, 1912, in the *Engineering Magazine* (New York), the present writer analyzed these causes in some detail, and stated his opinion that the increased cost of food, and the rising standard of comfort and luxury demanded by the workers, were the two primary and chief causes of this unrest, and of the general demand for higher wages.

In the present article it is intended to give facts and figures in support of this opinion, drawn chiefly from an important publication relating to the "Cost of Living of the Working-Classes," issued recently by the Statistical Department of the British Board of Trade (Cd. 6,955, 1913). This report, although dealing primarily with the conditions obtaining in Great Britain, covers the rise that has occurred in food prices in the leading manufacturing countries of the world. Other publications drawn upon are: No. 137 of the Annals of the American Academy of Political and Social Science, published in July, 1913 (this deals entirely with the minimum wage in its relation to the cost of living); an address by Prof. H. N. Dickson, and a paper by Prof. Fisher of Yale University, read and discussed at the British Association (Birmingham) meeting in September last. Publications of this kind, however eminent their authors, are not read by the general public. The purpose of this article is to render the valuable information contained in these reports, addresses and papers available for a much wider circle of readers, and to present certain of the data in more easily digested and attractive form.

The Increased Cost of Food.

On page 62 of the introductory summary of the Board of Trade Report on the cost of living, already referred to, there is a most valuable table showing by means of "index numbers" the changes in the level of food prices which have occurred in the United Kingdom and its colonies and in certain foreign countries in the years 1900–1912. In this comparison the year 1900 is used as a base year, and the retail or wholesale prices of food in each country are taken as represented by 100 in that year. Since comparative figures of this kind are much more illuminating when presented in graphic form, the author has constructed diagrams I. to IV. from the official data. The figures themselves, which represent a vast amount of time and trouble on the part of those responsible for their collection, are given for purposes of reference only in Table I.

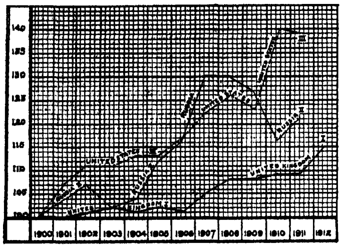


Fig. 1.—Diagram to show changes in the level of food prices in the United Kingdom, Russia, and the United States in the period 1900-1912.

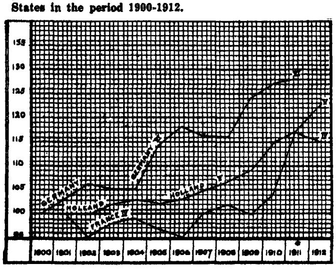

Fig. 2.—Diagram to show changes in the level of food prices in France, Holland, and Germany in the period 1900-1912.

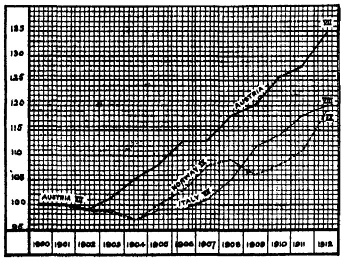

Fig. 3.—Diagram to show changes in the level of food prices in Austria, Italy, and Norway in the period 1900-1912.

Diagram I. gives the curve for the changes in food prices in the United Kingdom, Russia and the United States in the years 1900–1912. The rise is seen to have been practically continuous in all three countries, but whereas in 1911 the United Kingdom only showed an increase of 9 per cent, in Russia the increase had been 21 per cent, and in the United States the curve of prices had attained a level of 139, equivalent to an increase of 39 per cent on the prices of 1900. In Diagram II the price curves for France, Holland and Germany are presented in a similar manner and on a similar scale. Here we see that between 1901 and 1906, France benefited by a decline in food prices, the index numbers for which dipped down to 95 (or 5 per cent below the standard), in the years 1902 and 1906. Since 1907, however, the rise in food prices in France has been very marked, and in 1912 they reached their maximum of 117, equivalent to a rise of 17 per cent on the 1900 standard. In Holland the rise has been steady and continuous, and the curve has approximated in form to that of the United Kingdom, ending in 1912 at a level of 123, as compared with 115 for the United Kingdom. Holland and the United Kingdom, it may be pointed out, are the two free trade countries of Europe, and therefore, if free trade means (as its supporters declare) cheap food, one would expect to find the rise in prices much less striking than in highly protected countries. Whether this expectation is justified by the curves shown in Diagrams I. to IV., the writer of this article will not attempt to decide, since it would lead him away from the real purpose of this section, which is to present facts. The German curve shows a slight dip in the years 1907–1908, when the price of food in Germany declined, but since the latter year the rise has been very marked, and the curve ends in 1911 at a level of 128, equivalent to a rise of 28 per cent on the 1900 standard.

Diagram III. shows the curves for Austria, Italy and Norway, and calls for little comment. Italy and Norway benefited by a decline in food prices in the years 1902–1906. Since the latter year the rise has been steady but not very large, the curves ending at the levels of 119 and 120 respectively. In Austria the rise in food prices has been more marked and continuous, the increase being equivalent to 35 per cent in the 12 years.

Diagram IV., which gives the curves for the three most important colonies of the United Kingdom—Australia, Canada and New Zealand—is extremely interesting, and deserves close study and attention. Each of these colonies produces and exports food to the mother country in large quantities, and one would expect to find that the rise in food prices in these food-producing countries was less marked than in the United Kingdom or in the other industrial countries of Europe. In one case only is this so, namely, Australia, for up to 1911, the price curve for this colony had only attained a level of 103, and for the whole period the average has been 103½ In New Zealand the course of prices has been more irregular, and the curve rises to 109 in the years 1902–1903, and attains its maximum of 117 in 1908. The course of prices in New Zealand has thus shown a greater average percentage increase than in the United Kingdom. The price curve for Canada is, however, the most remarkable, for in this country the increase in the cost of food has been more marked than in any of the industrial or manufacturing countries, and the curve has steadily ascended until it attained the extraordinary level of 151 in the year 1912, or a rise of 51 per cent as compared with 1900.

Placed in the order of their "dearness" as regards the cost of food (in 1911 or 1912) we thus have the following list of countries: Canada, 151; United States, 139; Japan, 138; Austria, 135; Belgium, 132; Germany, 130; Holland, 123, Russia, 121; Italy, 120; Norway, 119, New Zealand, 116, Australia, 116; United Kingdom, 115; France, 115. A study of the curves given in Diagrams I. to IV. and of the summary of their meaning given above indicates therefore that during the past six years there has been in all countries (agricultural as well as industrial) a very marked rise in the price of food, and also that so far as the figures are available, the increases in the years 1911, 1912, 1913 have been greater than in any previous year.

The Causes of the Increased Cost of Food.

The causes of the increased cost of food in all countries, that is so clearly indicated in Diagrams I. to IV., are not perfectly understood and the opinions of economists are sharply divided upon this question. There are many who believe that the continued growth of the population of the world, the increased demand for luxuries, and the extravagant way in which the present generation is exhausting the material resources of the earth, is beginning to have its effect upon prices. Food and the other commodities of life are dearer, in the opinion of this school of economists, because, in relation to the increasing numbers who want them, they are becoming more scarce.

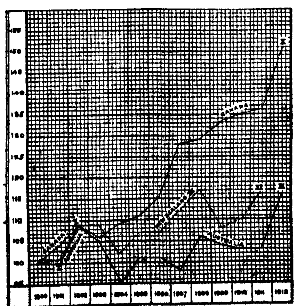

Fig. 4.—Diagram to show changes in the level of food prices in the three most important British colonies: Canada, Australia and New Zealand, during the period 1900-1912.

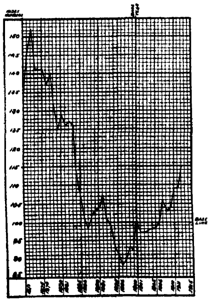

Fig. 5.—Diagram to show changes in the level of wholesale prices of forty-seven articles in the United Kingdom, 1871-1912.

This view finds expression in the presidential address of Prof H N. Dickson, before the members of the Geographical Section of the British Association, at Birmingham, England, in September last. In this address Prof. Dickson stated that "he had no desire to sound an unduly alarmist note, or to suggest that we are in imminent danger of starvation, but it would be well, even on the suspicion, to see if our information is adequate and reliable, and if our conclusions are correct, and not merely to drift in a manner which was justifiable enough in Saxon times, but which, at the rate things are going now, may land us unexpectedly in difficulties of appalling magnitude."

In support of this view, it must be noted that the population of the whole world is increasing by 20,000,000 persons annually, and that as water covers three quarters of the earth's surface, there is only one fourth available for the support of human life. The following quotation from a recent article by Mr. Chiozza Money, an English liberal political economist, emphasizes the teaching of Prof. Dickson's address, and will be read with especial interest in America:

"All mankind has for a basis no more than about 50,000,000 square miles of land, no small fraction of which is desert territory, or for other reasons uninhabitable. The parts of the world which are particularly favored in point of power supplies, whether of coal or mineral oil, or water, are few The easily-worked mines of iron, copper, tin, lead, zinc, etc , have been already creamed, with results which have made themselves evident in price As to timber, the world is using it much more quickly than it is growing it, and we have the extraordinary fact that the United States of America, which has some of the finest forests in the world, has hacked away at them so rapidly, that some sorts of wood are scarce in her vast territory."

The opposite view that food and other commodities are dear because gold has become more plentiful, finds its strongest advocate in Irving Fisher, Professor of Political Economy at Yale University. In an article upon "The Monetary Side of the Cost of Living Problem," contributed to volume 48 (July, 1913) of the *Annals* of the American Academy of Political and Social Science, and in a paper contributed to the Birmingham, England, *meeting of the British Association*, Prof. Fisher gives many reasons and arguments for believing that the present rise in prices is due to an inflation of money and credit, rather than to a scarcity of food and other commodities. His chief argument is based on the fact that the periods of high prices in the past have always coincided with some fresh discovery or more active exploitation of the gold resources of the world, and that periods of low prices have likewise coincided with a lull or setback in the production of the precious metals.

The following paragraph summarizes this argument:

"The rise in prices during the last fifteen years has not only been *great*, but general It applies to *almost* all commodities and to all countries for which we have figures If practically all the children in a certain school were stricken simultaneously with typhoid fever, we should reasonably suspect that there was some common source from which the germ had come If the prices of most commodities rise somewhat simultaneously, we, very reasonably, it seems to me, should attribute this rise to a common factor, rather than to various isolated causes relating to the commodities separately considered. In other words, on the basis of probabilities, it is reasonable to assume that the present general rise in prices is related to *some* common fact Since every price is tied to gold, and the supply of gold has increased during the last fifteen years, we would not then be unreasonable in suspecting, if not convicting, that fact of being responsible for the present high prices. No other important common cause has been suggested."

In his British Association paper, Prof. Fisher pleads for the appointment of an International Conference on the subject, a bill for which passed through the United States Senate last Spring, and states that this proposal has the support of the President and ex-President of the United States, and also of many high officials in the European capitals.

In the present writer's opinion, the increased prices of food and other necessaries of life may be, with some show of reason, attributed to a combination of the above two causes. The increased demand arising from the growing population of the world, and increase of luxury, have no doubt enormously stimulated the call for food and commodities of all kinds. At the same time, the increased output of gold and greater use of credit have *tended to cheapen these, in their relation to commodities*, and, therefore, one has to pay more in gold or silver to obtain the same amount of food than five or ten years ago. Which of these causes has had the most influence in bringing about the rise of the past five years, the writer will not attempt to decide.

Is the Rise in the Price of Food and Other Commodities Likely to Continue?

The question headlined is, of course, the practical one that all affected (either as buyers or sellers) by the recent rise in values, wish to have answered. The only figures that bear upon this question are those contained in the British Board of Trade Report already *referred to*, and they represent the course of wholesale prices of 47 articles of consumption in the United Kingdom from 1871 down to the present date—the year 1900 being employed as base year with a value of 100, and the values being expressed as before—as index numbers, in relation to that base. Diagram V. gives these values in the form of a curve, and the diagram certainly conveys little comfort to those who have been heavily handicapped by the rise in prices since the year 1900. Compared with the prices ruling in the United Kingdom from 1870 to 1880, present prices are low, and if history is to repeat itself, *many years will elapse before the maximum point of the* curve is attained, and the descent to a lower price level is commenced. Many things have changed however in the conduct of commerce and industry since the years that followed the Franco-German war, and it is quite possible that an analogy from the past, in this case, is an unsafe guide to the course of future events. That some high authorities believe that an era of high prices is before us, is proved however by the following extract from the British Association paper by Prof. Fisher:

"The outlook seems to many of us to indicate that the rise in world-prices is permanent, and is likely to be aggravated in *future years*. Under these circumstances, even though we cannot immediately apply remedies for lack of sufficient agreement, the sooner we can secure the necessary data to lead to such an agreement, the better."

Conclusions.

In view of the vast importance of the subject with which this article deals, there can be little doubt that Prof. Fisher's demand for the calling together of an International Congress to consider the problem is wise and timely, and will ultimately be adopted. As Prof. Fisher points out·

"The *great conflict of opinion at the Conference* will doubtless be as to whether the rise of prices means an inflation of money and credit or a scarcity of goods. If the result of its investigations should indicate that the rise of prices is chiefly a monetary phenomenon, this would indicate the importance of a monetary remedy, such as some plan for 'standardizing' monetary units, i. e., 'stabilizing' the general level of prices. But whether or not any such far-reaching remedy can be applied or even recommended, there are other and less ambitious remedies in the way of saving waste which ought to be carefully considered. Such, for instance, are the conservation of natural resources; the elimination of unnecessary middlemen; the introduction of co-operation where economies can thereby be effected; improvement of banking systems; removal of high tariff walls, etc."

An International Committee for making a geographical survey of the world's treasures of material wealth, as outlined in Prof. Dickson's British Association address, might also be appointed, and thus a general "stocktaking" of the earth's natural resources be carried out at the same time that the *important* problem of the rise in prices is being investigated. The writer of this article supports both proposals, and trusts that during the next twelve months some progress will have been made in obtaining the co-operation of statesmen in the leading manufacturing countries for this important work.

TABLE I INDEX NUMBERS OF THE CHANGES OF LEVEL OF FOOD PRICES IN THE PERIOD 1900–1912

Country	Nature of Index Number	1900	1901	1902	1903	1904	1905	1906	1907	1908	1909	1910	1911	1912
United Kingdom	Retail prices of 23 articles of food in London weighted according to workmen's consumption	100	100	101	103	102	103	102	105	108	108	109	109	115
France	Retail prices of 24 articles of food (including wine), fuel and lighting materials in Paris, weighted according to workmen's consumption .	100	100	95	98	99	97	95	100	102	100	104	117	115
Germany	Retail prices of 13 articles of food in Prussia, Bavaria, Baden and Wurtemburg, weighted according to workmen's consumption	100	103	106	105	105	114	118	116	116	124	127	128	(130)
Holland	Retail prices of 23 articles of food in 6 principal towns (unweighted) .	100	100	100	102	103	102	103	105	107	109	115	117	128
Italy	Contract prices of 14 articles of food supplied to 43 State colleges in various parts of the country (unweighted) .	100	100	90	99	97	99	90	101	105	112	114	118	120
Norway	Retail prices of all articles of food (26 specified) in Christiania weighted according to workmen's consumption . . .	.	100	99	99	97	100	103	108	109	106	108	111	119
Russia	Wholesale prices of 30 articles of food at representative markets (unweighted) .	100	104	107	102	104	112	116	130	130	127	116	121	. . .
United States	Retail prices of 15 articles of food in 39 principal cities weighted according to workmen's consumption .	100	105	111	111	113	113	117	122	126	133	140	130	.
British Dominions Canada	Wholesale prices of 78 articles of food (including fodder) at representative markets weighted according to national consumption . . .	100	104	109	106	109	111	115	128	129	133	135	130	151
Australia	Retail prices of 11 articles of food (besides soap, starch, washing blue, kerosene and candles) in the 6 capital cities, weighted according to national consumption		100	109	105	95	101	101	98	106	104	108	103	116
New Zealand	Wholesale prices of 17 articles of food at representative markets (unweighted)	100	101	109	109	102	107	107	112	117	108	110	116	. . .

The Biggest Bird That Ever Lived

By R. W. Shufeldt, M. D.

DURING the Summer of 1913, while engaged in describing and photographing the specimens representing the fossil remains of vertebrates in the extensive collections belonging to the American Museum of Natural History, the United States National Museum, and the Peabody Museum of Yale University, I met with the fragments of the lower long leg bones that belonged to an extinct bird of enormous size. They were completely fossilized, and had been discovered by a member of the Expedition of 1912 sent out by the American Museum of Natural History in the Wasatch of Wyoming. Geologists are pretty well agreed that this particular region is some 2,500,000 *years old*.

These fossil remains consisted of two immense toe-joints and parts of the trochlea of the tarso-metatarsus of an adult individual. The tarso-metatarsus in a bird's leg is the last of the three of the long bones of that limb; the trochlea are those projections at its distal end which articulate with the toe-bones.

This was all that had been found of a bird giant which had flourished over two and a half million years ago in the central region of this country. It was not all that we knew about it, however; for, many years ago, the late Prof. Cope had described, in the *Proceedings* of the Academy of Natural Sciences of Philadelphia (1876, II) and subsequently in the Report of the U. S. Geographical Survey West of the 100th Meredian (Vol. IV, p. 70), the fossil remains of a bird of gigantic proportions, of which he said that "this species was of large size, the proximal end of the tarso-metatarsi being nearly twice the diameter of that of the ostrich. Its discovery introduced this group of birds to the known fauna of North America, recent and extinct, and demonstrates that this continent has not been destitute of the gigantic forms of birds now confined to the Southern hemisphere fauna." This distinguished palæontologist named this long-extinct species *Diatryma gigantea*, and considered it to be quite distinct from any of the existing true ostriches.

We know that an old male African ostrich will grow to be at least eight feet tall, and Cope surmised, in his description of *Diatryma gigantea*, that it was a bird twice the size of an adult ostrich; in other words, it may have attained a height of some fifteen or sixteen feet, or about three times the height of an ordinary man.

It would seem to have belonged somewhere in the group of great flightless birds with keelless sternums known as the *Ratitæ*, or in the Supersuborder *Dromæognathæ* of my own Classification of Birds. Doubtless it was ostrich-like in appearance while not directly allied to that genus, or still less to the moas of the New Zealand group of islands, of which there were some twenty species, now all extinct; of these *Dinornis maximus* was, without doubt, a bird that grew to be at least twelve feet tall, or four feet taller than the tallest of existing ostriches (Newton).

Upon comparing the fossil remains of this extinct bird of ponderous proportions, belonging to the American Museum of Natural History, with those of Cope's *Diatryma gigantea*, I at once recognized the fact that it, too, belonged in the same genus or the genus *Diatryma*, and I have since bestowed upon it the name *Diatryma ajax*. Upon measuring the bones and fragments of bones representing it, it was apparent that these were from a form considerably larger than Cope's *D. gigantea*, and could such a thing ever have happened as to have an old male African ostrich stand beside a full-grown individual of this extinct, gigantic bird of the Eocene of Wyoming, the former would have appeared, by way of comparison, a veritable pigmy in its proportions.

In order to appreciate the probable *size of Diatryma ajax* I have made a drawing for the purpose. The ac-

accompanying illustration is based on that drawing.

The representation of *D. ajax* here shown is intended merely to give its size and *height* as compared with an ostrich and a man, and in no way intends to be a *restoration of this species*; for, up to the present time, we have not the required fossil bones of either *D. gigantea* or *D. ajax* to give us any idea as to the *forms* they had. The illustration is merely a generalized ostrich form to give the reader an idea as to how it would have towered above any one of us or above an ostrich. As here represented, *D. ajax* would have been a bird about twenty feet in height, but if the shafts of the long bones of the leg were fashioned as they are in an ostrich and not as in a moa, it could easily have been a much taller bird than that—that is, it could have attained a height of between twenty-five and thirty feet.

Diatryma ajax, the extinct, ostrich-like bird of the lower Eocene of Wyoming, was a much larger and taller bird than Cope's *Diatryma gigantea*, and what is more, it towered above the *Dinornis maximus* of New Zealand, which was, for many years, the tallest extinct bird known to science.

The Decision in the Kodak Film Case

ON September 9th, 1913, an interlocutory decree was handed down in the case of the Goodwin Film and Camera Company against the Eastman Kodak Company. The question at issue was the validity of patent 610,861, granted to Hannibal Goodwin on September 13th, 1898, for "improvements in photographic pellicles and processes of producing the same," in other words, nothing more or less than the well-known kodak film. The court upheld claims 1, 6, 8 and 10 of the patent. The Eastman Kodak Company appealed from the decision, but on appeal the United States Circuit Court of Appeals for the second circuit affirmed it. The decision, written by Judge Coxe, upholding, as it does, a patent which covers a process that forms the basis of an enormously wealthy industry, is of such importance that we publish, in the following paragraphs, an abstract of it.

Hannibal Goodwin was a clergyman residing at Newark, New Jersey, for thirty years prior to his death, which occurred December 31st, 1900. His salary was small, and for ten years prior to his death he had no regular charge. He was interested in chemistry and spent much of his spare time in chemical experimentation and research. The necessity for a transparent, sensitive pellicle for use in roller cameras had long been felt, and Goodwin, though hampered by his inadequate surroundings, undertook the task of supplying it. The patent specification points out the manifest objections to supports of glass and of paper in combination with gelatin and other substances, and proceeds to state how they may be avoided. The patentee says:

> "I have provided a pellicle the principal ingredient of which is nitrocellulose, or any equivalent . . . which is transparent, and insoluble in the usual developing, fixing and intensifying solutions or liquids used in photography. . . . In carrying out the invention, I provide a suitable surface, such as that of glass, and flow over the same a solution of nitrocellulose dissolved in nitrobenzole or other non-hydrous and non-hygroscopic solvents . . . and diluted in alcohol or other hydrous and hygroscopic diluent."

When dry, this solution forms a flexible transparent sheet or pellicle which is insoluble in any of the fluids employed in dry plate photography. The foil when stripped from the glass constitutes a supporting pellicle for the sensitive film. The specification states further that previous efforts to provide a transparent and flexible pellicle have been failures because they did not possess the properties of glass and were incapable of resisting the usual developing, fixing and intensifying solutions used in photography.

Hannibal Goodwin claimed that he had produced a film which is capable of resisting such fluids and of sufficient smoothness, hardness and toughness of surface for service in a roller camera. He said that in carrying out the invention he provides a suitable surface such as glass and flows over it the solution of nitrocellulose (as distinguished from "commercial celluloid") dissolved in nitrobenzole or other solvent not containing or capable of absorbing water. The equivalents for nitrobenzole are acetate of amyl and those non-hydrous, non-hygroscopic fluid solvents of nitrocellulose which do not mix with water, are not greasy, and are of slow volatility. Nitrocellulose when so dissolved and flowed over a smooth plate produces a smooth, transparent, imporous, impermeable film capable of being subjected to the photographic fluids without being affected thereby. It is further stated that the solution thus obtained by dissolving the nitrocellulose is diluted with alcohol or other similar diluent which serves to dilute or expand the volume of the dissolved nitrocellulose or increase its fluidity. The diluted solution is then applied to a smooth and hard surface, from which it may be stripped when dry.

The claims in controversy are as follows:

> "1. An improvement in the art of making transparent flexible, photographic-film pellicles, the same consisting in dissolving nitrocellulose in a menstruum containing a hygroscopic element and an element which is non-hygroscopic, the non-hygroscopic element being, of itself, a solvent of nitrocellulose, and of slower volatility than the hygroscopic element, depositing and spreading such solution upon a supporting-surface, and allowing it to set and dry and harden by evaporation, and spreading a photographically-sensitive solution on the hardened film, and drying the film, substantially as set forth."
>
> "6. An improvement in the art of making transparent flexible and elastic photographic pellicles, the same consisting in dissolving nitrocellulose in an eventual celluloidal menstruum which is anhydrous and non-hygroscopic, spreading such solution upon a supporting surface, allowing it to dry and harden, spreading photographically-sensitive matter, thereon, and again drying and stripping the pellicle from said support, substantially as set forth."
>
> "8. The process of making photographic pellicles, which consists in subjecting nitrocellulose to the action of a menstruum combining fast and slow evaporating solvents, the slow evaporating solvent being non-hygroscopic and non-greasy in nature and quality, and acting as an eventual solvent as described, spreading the solution upon a support and setting the same by evaporation, then applying photographically-sensitive matter and stripping, all substantially as set forth."
>
> "10. As a new article of manufacture, a transparent film-support for photographic purposes, the same consisting of a thin, non-greasy, film, foil or pellicle of a dried and hardened celluloidal solution of nitrocellulose, combining in addition to the following essential properties of glass-plate supports, viz., insolubility in developing fluids, insensibility to heat and moisture, imporosity of structure, and hardness, smoothness, and brilliancy of surface, the further desirable properties of exceeding thinness, lightness in weight, toughness in texture and elasticity in flexure; as and for the purposes specified."
>
> "12. The process of manufacturing photographically-sensitive pellicles, consisting of flowing a non-photographically-sensitive solution of nitrocellulose dissolved in a non-hygroscopic liquid, or a liquid which is eventually non-hygroscopic and drying and hardening such compound into a support for the photographically-sensitive emulsion and imposing on such support the said sensitive emulsion, substantially as set forth."

Claim 10 covers the film support as a new article of manufacture, and the other claims cover the process by which the pellicle is produced.

An examination of the first claim will demonstrate sufficiently the various steps of the Goodwin process for making a transparent, flexible photographic-film pellicle.

At the time of Goodwin's invention, the art was vehemently demanding, as a substitute for the glass plates then in use, a transparent photographic film capable of supporting the sensitive emulsion necessary in photography, and also capable of being rolled up. Goodwin entered the field as an inventor, for the sole purpose of overcoming the difficulties then existing, and he did so when, speaking broadly, he discovered the process of dissolving nitrocellulose in a menstruum containing nitrobenzole and alcohol or their equivalents, and then spreading the sensitive emulsion on the hardened film. He was subjected to almost unprecedented delays and disappointments in the Patent Office, which it is unnecessary to consider in detail, but he held tenaciously to his original conception of the invention.

There is no proof in the record to support the contention that his process was known by others prior to the date of his application. On the contrary, the necessity for the patented pellicle became more and more apparent and the demand for it more and more insistent, and many efforts were made to meet the demand, but with partial success only.

In 1887 an article appeared in the *Photographic Times Almanac* in which a well-known authority on photographic subjects, Andrew Pringle, points out the pressing needs of the art in language which is prophetic of the Goodwin invention. He says:

> "When we get a support such as I have indicated, transparent, flexible, and in lengths, tourist photography will make a stride that will throw into obscurity all previous advances."

And yet at the time this article was published, there was in the Patent Office an application showing that this stride had actually been taken.

It is unnecessary to advert to the other evidence in the record showing priority of invention in Goodwin. In addition to the presumption arising from the patent itself, we have his clear description of the process which any intelligent chemist would understand and which, if followed, must produce the desired film. Stripped of the unnecessary technical verbiage, which was largely produced by the proceedings in the Patent Office, Goodwin's statement is so plain that it would seem that a neophyte might follow the instructions successfully.

Goodwin's application, as filed in 1887, disclosed, for the first time, the fundamental and essential features of a successful, rollable film. Nothing in the prior art shows Goodwin's process and the proposition that any skilled chemist, familiar with the art as it existed prior to May 2nd, 1887, could construct the Goodwin pellicle cannot be maintained. The defendant's brief says.

> "The Eastman Company, in 1888, devised and introduced its first 'Kodak' camera. . . . This 1888 Kodak . . . marked the beginning of amateur photography."

but it is not pretended that a film other than one having a paper support coated with sensitized gelatin, was used prior to Goodwin's invention, or, indeed, prior to May 2nd, 1887. The proposition that these paper films were used because they were inexpensive and thus available for trying out the film-roll system is not persuasive.

The Eastman Company did not commence its experiments, looking to the substitution of pyroxyline for paper, as a film support, until the latter part of 1888. These experiments were continued by Henry M. Reichenbach, the company's chemist, until February, 1889, and on April 9th, 1889, he filed his application for a patent as assignor to the Eastman Dry Plate and Film Company, and promptly received a patent dated December 10th, 1889. During all this period beginning with the experiments and ending with the patent, Goodwin's application was lying in the Patent Office. It may be that his process was an improvement on Goodwin and that during the life of his patent he was entitled to the exclusive use of such improvement, but it can have no retroactive effect, it cannot destroy or limit an invention which was *in esse* before his invention was conceived.

There is no evidence that anyone ever did make the Goodwin pellicle prior to his invention, and the court was convinced that no one could have made it by following the direction of Parkes or David (cited in reference of the defendant).

It is unnecessary to consider the question of invention in all the details pointed out in the defendant's briefs, for the reason that Goodwin was the first to dissolve nitrocellulose in nitrobenzole or its equivalents diluted in alcohol or its equivalents. This being so, his patent is entitled to a construction broad enough to enable its owner to reap the profits which naturally and fairly belong to the invention. The invention is one of more than ordinary merit, and the claims should not be so construed that anyone may safely infringe who has wit enough to substitute equivalents for the elements named in the patent, and to add or subtract therefrom, so long as the menstruum contains a hygroscopic and a non-hygroscopic element, the latter being a solvent of nitrocellulose and of slower volatility than the former. If the defendant uses a process having these elements, it matters not what else it uses or that its method is an improvement on the patented method.

It is not necessary to enter upon a discussion of the Reichenbach interference further than to say that this, as well as most of the complications in the case, would have been avoided had the Goodwin patent gone to issue in due course, as it should have done. The long delay and the contradictory rulings of the Patent Office would have discouraged an inventor who had not supreme faith in the justice of his cause. If Goodwin made a generic invention it follows that he is entitled to hold as infringers those who used the equivalents of nitrobenzole and alcohol. In the process of the patent and of the defendant nitrocellulose is used. In both it is dissolved in a menstruum containing a high-boiling, non-hydrous, non-hygroscopic solvent like nitrobenzole or its equivalents and a diluent like alcohol or its equivalents. In both the processes of the defendant, nitrocellulose is dissolved in a menstruum consisting of a high-boiling, non-hydrous, non-hygroscopic solvent and a diluent of wood alcohol. In the process of 1898, the solvent was amyl-acetate 5 parts, fusel oil about 16 parts and camphor 3 to 5 parts. The diluent was wood alcohol 104 parts. In the 1902 process, the solvent was fusel oil 16 parts and camphor 3 parts. The diluent was wood alcohol 40 parts and acetone 40 parts. There can be no doubt that the defendant uses nitrocellulose and the diluent of the patent, viz., alcohol—wood alcohol being expressly referred to in the patent as an example of a diluent having a low boiling point and a relatively quick evaporating quality. The only debatable question relates to the equivalency of the defendant's solvent and it cannot be doubted that the combination of fusel oil, camphor and amyl-acetate of 1898 process and the fusel oil and camphor of the 1902 process are equivalents of the high-boiling, non-hydrous, non-hygroscopic solvent of the patent. It matters not that the defendant's process produces better results than that of the patent. Assuming this to be true, it does not give the defendant the right to use Goodwin's discovery because it has introduced improvements. It would be strange, indeed, if during the fifteen years which elapsed from the date of the Goodwin application to the adoption of the 1902 process there had been no progress in the art. Undoubtedly there was progress, but one cannot use a patented invention because he has improved it.

Goodwin was the first to produce a transparent sensitive pellicle for use in roller cameras. The conclusion naturally follows that his patent is entitled to a liberal construction. Doubts should be resolved in its favor, and care taken not to confuse the art at the date of issue with the art as it existed at the date of the application, eleven years before. So considered and construed, the claims in controversy are valid and infringed.

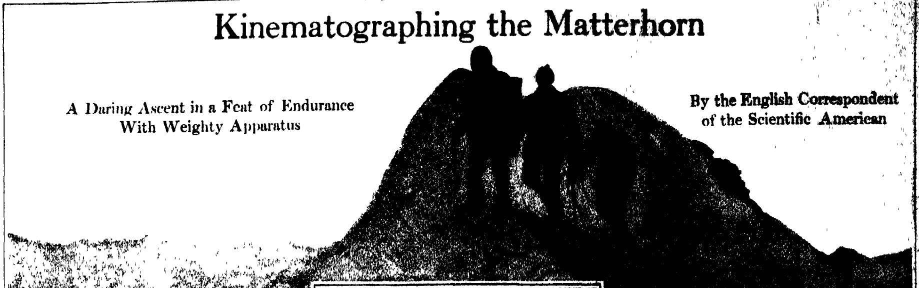
A Bottle-stopper that Locks

A BOTTLE stopper that locks is a recent Paris idea, and will be very useful for keeping fine liquors and the like out of the reach of persons for whom they are not intended. It can also be used for protecting inflammable or dangerous liquids so as to avoid accidents. A metal cap fits over the bottle neck, and it has a small felt-lined collar inside which serves to fit around the rim of the bottle. The collar is pressed on by turning a winged nut, and when all is in place, a small arm comes down alongside the wing of the nut so as to allow of running a padlock through the two holes. This prevents any turning of the screw and keeps the bottle tight shut.

Kinematographing the Matterhorn

A Daring Ascent in a Feat of Endurance With Weighty Apparatus

By the English Correspondent of the Scientific American



Starting upon the descent from the crest.

AMONG the many peaks forming the Alpine chain of Switzerland, which are so familiar to the tourist, the Matterhorn never fails to compel attention from its peculiar pyramidal formation, jutting in stately loneliness above its rugged fellows. It is a peak which possesses unfathomable fascination to the mountaineer, owing to the extreme difficulty and danger in scaling its crest, and because of the atmosphere of tragedy with which it is invested. It was not until July, 1865, that its topmost rock was trodden by human feet, and that pioneer effort made by Whymper proved most disastrous, inasmuch as four of the party fell 4,000 feet and were dashed to pieces.

Although, since that tragic year the mountain has been scaled upon numerous occasions, yet it is a feat which must not be attempted by any but the most experienced climbers, and then only with the assistance of thorough expert guides The latter, cognizant of its fearful steep precipices and menacing crags, will not essay the attempt unless the mountain is in first-class condition, and the weather is fine. To-day the peak, which rises to an altitude of 14,705 feet, may be ascended upon three sides, and the route followed is determined by prevailing conditions. However, it is by no means unusual for a party to be held up for three or four weeks by adverse weather conditions upon the higher reaches, and, frequently, an expedition has to be abandoned entirely, owing to the brief duration of the climbing season

Therefore, when Mr Frederick Burlingham of the British and Colonial Kinematograph Company, who is himself an expert climber, intimated his intentions to make an ascent and to kinematograph the peak during the climb, his proposal was received with ridicule. At least two days would be involved in the task, and there was every possibility of the party becoming stalled, in which event a serious situation would be precipitated Then again, the weight of the apparatus necessary for taking the "movies" served as an additional deterrent The majority of climbers, owing to the difficult character of the ascent refuse to be hampered in any way whatever; they even will decline to take a snap-shot camera with them

The kinematographing suggestion certainly was somewhat daring, inasmuch as bulky and weighty apparatus would be unavoidable Mr. Burlingham secured the lightest and most reliable instruments he could find, but even then the weights could not be kept down very much The camera itself weighed 33 pounds, the tripod 22 pounds, while the film and spool boxes brought the complete weight to nearly 70 pounds. This was above that which was absolutely indispensable in the outfit to be carried, such as ropes, extra clothing, provisions, and refreshment.

The operator secured the assistance of two of the most reliable guides in Switzerland. The leader, Gabriel Zumtaugwald, accompanied Mrs Bullock Workman on her expedition to the Himalayas, while Heinrich Julen was familiar with the Swiss mountains through and through. In addition, two first-class porters, who were also expert climbers, accompanied the party to carry the apparatus, and they all succeeded in accomplishing a feat of endurance which has never been equalled in the playground of Europe.

The guides and porters, although willing to make the attempt, frankly stated their convictions that the effort would prove a failure, and did not hesitate to point out the many and extreme dangers attending the task. However, the operator would not be dissuaded, and accordingly the itinerary was mapped out very carefully.

Climbing the "shoulder" of the Matterhorn.

It was decided to climb the mountain upon the Zmutt side and Zermatt (5,315 feet) was selected as the starting point. Here the party remained, watching the barometer and the behavior of the weather on the mountain top. For two days the crest was assailed by a terrific gale, which blew away the freshly fallen snow in clouds, and this tempest was followed by two days of perfect sunshine. The barometer standing very high and steady, the party decided to start on July 1st, and to push ahead so as to gain the Matternhorn *cabine* at 10,745 feet the same day, and to spend the night in this elevated hostelry.

In order to conserve the energies and endurance of the porters, it was decided to load the equipment upon three mules and to drive them as far as possible up the mountain side. They started off amid the cheers of a huge crowd.

The going at first was easy, the party reaching the Schwarzsee hotel, having luncheon and leaving at 1:30. The path lay over the dangerous Hörnli ridge. This trail winds along the brink of forbidding precipices, and, at the most awe-inspiring places, moving pictures were taken to demonstrate the partiality of the mules for the outer edge of the trail, which has often been described, but which those who have never been on a mule's back among the mountains scarcely can believe. The explanation however is simple. The animal takes the more dangerous-looking part of the narrow path merely to prevent his load knocking against the mountain wall on the inside.

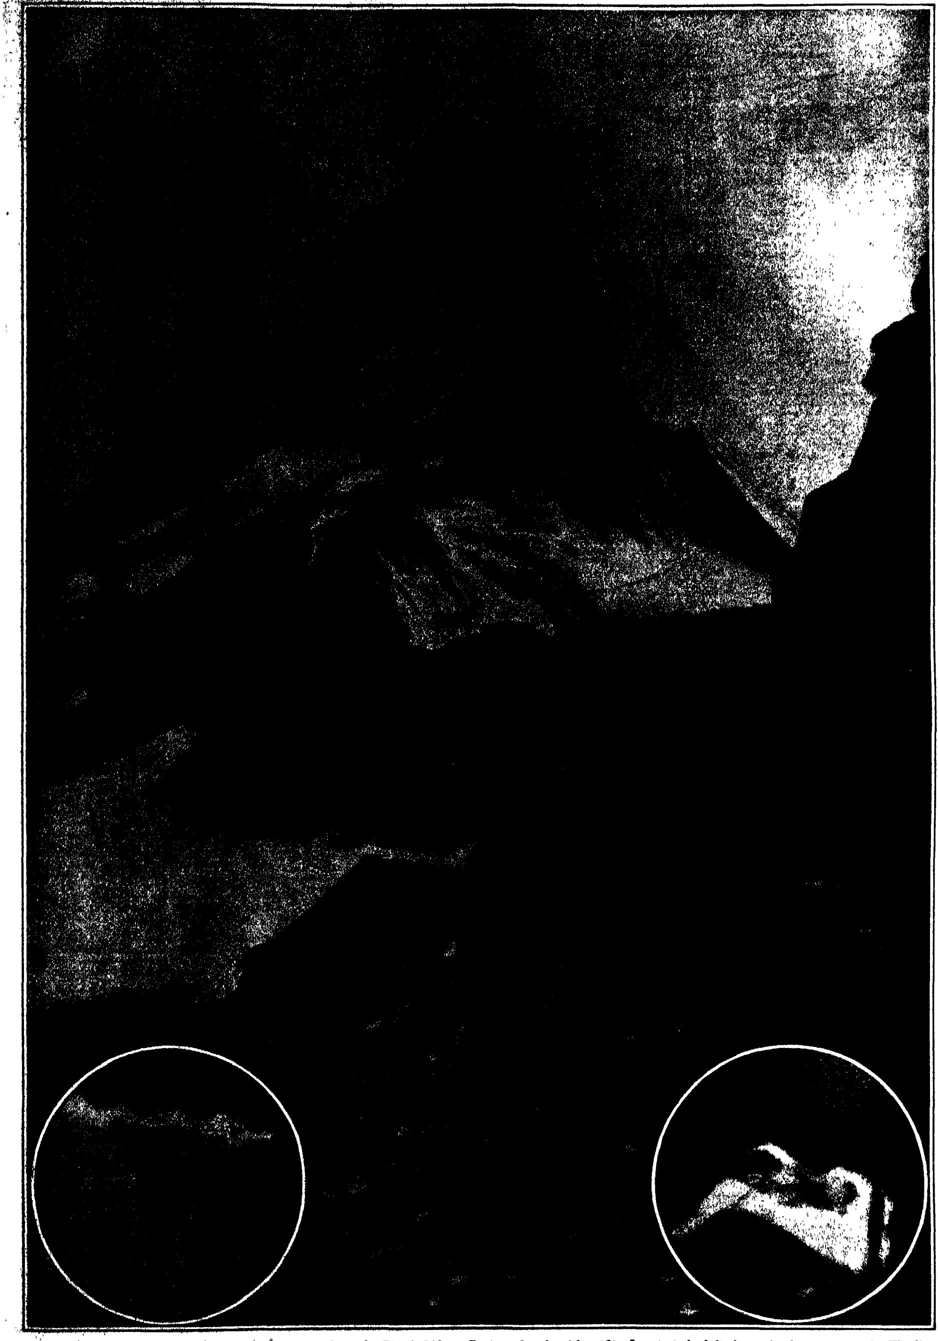
The party did not succeed in traversing the Hörnli ridge very far by animal effort. First two mules were turned back, and the journey resumed with one. But the snow became so deep that this animal floundered hopelessly, and at last, was abandoned, the two porters shouldering the weighty and cumbersome apparatus, while the others assumed their proportions of the remaining equipment. Progress was somewhat slow as the ridge was covered thickly with snow and ice, and this state of affairs did not augur well for the attack upon the peak proper the next day.

Although the going was difficult the *cabine* was reached early in the afternoon. This hotel, at more than 10,000 feet above the sea, is impressive in its loneliness, and like all elevated hostelries provided essentially for the convenience of the daring, has its own peculiar tariff. The room costs $5 a night if no food is supplied, but if the latter is partaken beneath its roof, and charged extra, the cost of the room is $2.50. But, seeing that every ounce of provisions as well as wood has to be brought up by porters, and taking into consideration the limited number of guests, the charges are not high.

The climb proper was commenced early the next morning, the party setting out at 2:30 A. M.—an hour later than had been arranged. The stars were shining brightly, the wind had blown itself out, but the cold was intense. Roped up and armed with lanterns, the party proceeded to make their way up the ice-covered crags. Climbing amid such dangerous surroundings, the flicker from a hand lantern produces strange sensations in the mind of an amateur, but to the experienced mountaineer it offers little disadvantages, although a few minutes must elapse before one becomes accustomed to the glimmer. The party soon found that the peak was far from being in a condition conducive to rapid traveling, as, in the darkness they had to cut their way step by step through some of the most dangerous places, with a sheer drop of hundreds of feet onto the glaciers looming out indistinctly below.

Despite the hindrances, smart progress was maintained; in fact, the guides themselves urged a slower pace, as the rarified air was somewhat exhausting. Indeed, Burlingham, the operator, lost his breath at this point, and did not regain it full until he once more

(Concluded on page 264.)



Pyramidal aspect of the superb Matterhorn as seen from the Hörnli Ridge. Party and mule with outfit. Insert at the left shows the deep snow on the Hörnli Ridge, where mule had to be abandoned. The one at the right pictures the party at the summit of the peak.

KINEMATOGRAPHING THE MATTERHORN.

The Problem of Our Navy

IV.—The Price We Pay for Self-sufficiency and Unpreparedness

By the Editor

THE present indifference to the naval and military needs of the country is traceable to several causes and conditions, first among which we do not hesitate to place the biased and one-sided historical teaching given to our children in the public and high schools, supplemented, it must even be admitted, by that of some of the text books of our higher institutions.

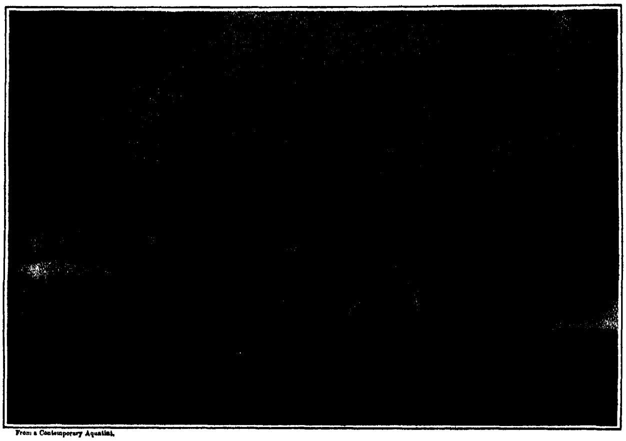
The inculcation of the doctrine of American invincibility begins with the instruction of the American "Schoolmarm"—efficient and worthy though she is—and one lasting result of her patriotic fervor is that the average American youth passes out into the work-a-day world with the deeply-ingrained belief that, since the United States has emerged victorious from every conflict in which it has been engaged, it is practically invincible, and therefore may contemplate any possible wars of the future with the conviction that the defeat of the enemy is inevitable

Nevertheless, *it is a fact that not once in its history has the naval and military strength of the United States been put to the supreme test against a first-class power.*

The war of 1812? No, not even then; for at that time Great Britain was engaged in the stupendous struggle of the Napoleonic wars—she was fighting for her very existance, and the storm center lay not in the New World, but the Old. The Mexican war of 1848 was waged against a feeble State; and not much stronger was Spain in 1898.

The misleading tuition of the schoolroom is subsequently aided and abetted by a perfervid political oratory, under the spell of whose sonorous and impassioned sentences the successes of our wars are apt to be swelled to an importance far beyond their merits, and their failures absolutely ignored.

And lastly, there is the daily press, which seemingly is unable to record the simplest military exploit without suffering from an acute attack of superlativitis, and under whose facile pen an affair of outposts becomes a serious engagement, and a skirmish expands to the dignity of a battle big with the fate of nations



From a Contemporary Aquatint.

" A war of arms, brought on by a programme of peace."—WOODROW WILSON.

Duel between "Chesapeake" and "Shannon."

Some day, someone will write the story of the great battles of the world from the viewpoint of the inefficiency of the losing side When that is done, there will be a sensational readjustment of values. It yet remains for some competent critic, preferably a civilian, to write such a history of the Spanish-American war, and prove how greatly the woeful inefficiency of the Spanish navy facilitated the victories of our own It may be said of the enemy that from the opening gun at Manila to the capitulation at Santiago, he literally "did the things he ought not to have done, and left undone the things he ought to have done." This is well understood by our naval officers. Although the navy lived up to its fine traditions, and both officers and men won every distinction that the opportunities of the war may have offered, we have frequently heard these same officers deplore the fact that the American public was liable to draw exaggerated conclusions from the victories of Manila and Santiago. Thus we learn from "War-time in Manila," a recent book from the pen of Rear-Admiral Bradley A Fiske, who took part in the battle of Manila Bay, that the Spanish admiral might have rendered Dewey's expedition not only futile, but overwhelmingly disastrous, if he had but placed his fleet under the protection of the powerful modern guns of Manila city, instead of under the forts of Cavite. Here is the situation as described in the Admiral's own words:

"Now what would have happened if the Spanish had put their fleet close in front of the city, as we expected they would do? The conditions for firing would have been almost perfect on the solid protected positions of the shore guns. . . . One hit from one of those 9.2-inch guns would have done irreparable injury to any American ship, because no American ship was armored and we had no means of making repairs. Almost any such hit would have sunk the "Petrel" or disabled any of the other ships. . . We should have had to fight a much longer time to destroy the Spanish ships, and during every instant we should have been exposed to a much greater volume of fire. We would have received tremendous injuries. If the Spaniards had done as they should have done, and blown up the machinery in the Arsenal, where would we have gone to repair our injuries? San Francisco was 7,000 miles away. Note.—Since writing the words above, fifteen years have gone by. *My present opinion is, and has been for several years, that if the Spaniards had placed their fleet where it would have been supported by Manila's guns, they would have sunk every American ship. Dewey could not have retreated fast enough to save his ships, after the injuries had once begun to arrive; and even if he could (and would) whither would he have gone?*"

So also at Santiago. Not alone were our ships overwhelmingly superior in size and gun power, but the Spanish admiral, instead of scattering his ships in different directions, as he should have done when he emerged from the harbor, strung them out along a lee shore and in such a position that they could not maneuver. The American fleet was able to choose its own distance and batter the Spanish cruisers to pieces under all the easy conditions of a summer target practice It may be said of the Santiago as of the Manila fight that it was a battue rather than a battle.

Now let it be clearly understood that the facts we have given above are quoted, not with the purpose of detracting from such credit, and there is much of it, as is due our Navy for its overwhelming victories, but merely to establish the truth that never, as yet, has the modern American Navy been put to the supreme test of engaging, with equal forces, a first-class naval power; and that *to imagine we can afford to enter into a future war without matching ship with ship and gun with gun in equal strength and with equal numbers, is to lend ourselves to a delusion and a snare.*

True it is that in the war of the rebellion we established our standing as a great military nation; but so far as that war affects the problem of our Navy, its one great lesson is that of the enormous folly and the stupendous extravagance of our drifting along in a chronic condition of unpreparedness for war.

For if the country had possessed an adequate navy, fully manned and equipped, the war, instead of dragging its weary length through four long years, with their enormous sacrifice of life and treasure, might have been won in six months' time. The South sent out its merchandise and received in exchange the munitions of war through its Southern ports. Had the Government possessed an adequate navy, these ports would have been shut in at once by a strict blockade; and the sheer lack of the munitions of war would have forced the South to a speedy capitulation. As it was, our chronic state of unpreparedness imposed upon the country the gigantic task of creating in time of war both the naval and military forces that were necessary to push the war to a successful issue.

In no sphere of human activity does the "penny-wise pound-foolish" policy demonstrate its inexcusable and costly folly so clearly as in this matter of naval and military preparedness. Times without number, history has proved that an efficient navy is a most economical investment; and that "a war of arms brought on by a programme of peace," as President Wilson has characterized the war of 1812, is a policy of the wildest extravagance.

There have been periods in the history of this country when the provision of the moneys necessary to build, equip and maintain a fleet adequate to its necessities, would have proved to be a venture yielding one thousand per cent on the investment.

Is the statement disputed? Then look at our annual pension roll of $180,000,000—a legacy of our unpreparedness! *The total cost of pensions to date, due to the civil war, has been four thousand millions of dollars—sufficient to have built nine dreadnoughts per annum for the past forty-seven years.* The pension appropriation for 1914 will be about $180,000,000; an annual draft on the Treasury which would suffice to build about nineteen superdreadnoughts.

First cousin to the popular belief that our record in war shows us to be invincible is the equally foolish belief that the mere possession of dollars and men, pride and pluck, suffices to make us a first-class military people. It is positively amazing that in a country which leads the world in the number and excellence of its schools, the magnificence of its public libraries, and the far-reaching activities of its daily press, there should still prevail a widespread belief that the naval and military strength of this country can be expressed in terms of its area and population, the undeveloped resources of its mines, farms, and forests, and the length of its roll-call of multi-millionaires.

How many of the people of this country understand that our vast national wealth in its present undefended condition, and our commanding geographical position, by exciting the cupidity and the jealousy of rival States, are a positive source of weakness and a powerful predisposing cause to a war for which we are ludicrously unprepared.

The day of undisciplined levies and extemporised navies has gone by, never to return; for the trend of naval development in the past few years has been such as to put a heavy premium upon preparedness and a heavy discount upon the mere possession of the raw materials of war. It takes three years to build a battleship and another year to get it into efficient fighting condition; it takes four years to produce an efficient gunner or petty officer, seven years at Annapolis and aboard ship to bring a junior officer up to full efficiency; from twenty to twenty-five years to produce a captain equal to the command of a battleship, and from twenty-five to thirty-five years to produce an admiral equal to the enormously complicated and difficult task of carrying a huge modern fleet successfully through a naval campaign. The naval wars of the future will be short, sharp and decisive. They will be decided just as soon as the far-flung screens of scouts and cruisers have got in touch with each other, and have brought their respective fighting lines of dreadnoughts together. When that has been done, *the fate of the contending nations will be a matter not of days or even of hours, but of minutes. The battle of Tsushima, which brought Russia to her knees, was won in forty-five minutes from the firing of the first gun!*

War is infinitely more costly than battleships; and both history and common sense combine to teach us that there is no agency so potent in preventing war as a battleship line sufficiently strong to preserve the peace. *It is the magnitude and preparedness of the German naval and military forces that has secured to Germany the forty years of unbroken peace, during which that country has so greatly developed its home industries and built up a merchant marine that is the wonder and admiration of the world.* (Thanks to our geographical position we need carry no such burden of military forces as Germany—an adequate navy will give the needed security.) It is the realisation by Great Britain of the importance of the command of the sea as expressed in her magnificent navy, that has made her the dominant world power and maintained her shores inviolate for centuries against the racial hatred and the military ambitions of the great powers of Europe.

The policy which has led Great Britain to build up her enormous navy is a policy not of war but of peace. Had she restricted her naval appropriations as we have done, she would long ago have been plunged into a war, the cost of which, in loss of ships and commerce, would have paid for her navy, great as it is, ten times.

And what of ourselves? Shall we lay to heart the lesson of that stupendous pension roll of $180,000,000 and hasten to bring up our navy to a standard of strength that will insure a lasting peace, or shall we, as in 1812, drift into another "War of arms brought on by a programme of peace?"

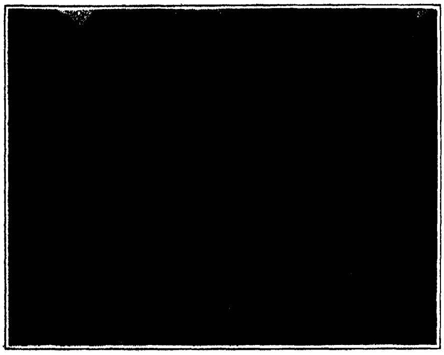
Crossing the River on a Wire

THE primitive bridge herewith illustrated is one which was made for practical use by a party of government surveyors in the Rocky Mountains, and is illustrative of the difficulties which are being constantly met and overcome by such "advance guards of civilization." It consists of two strands of telephone wire, borrowed from the Forest Service, stretched between two trees. The "bo's'n's seat" and "trolley" consist of a loop of the same kind of wire and a billet of wood. The bridge served for the transportation of a crew of men with instruments and supplies for several days work.

Ticket-printing Machine

IN Europe, railroad tickets are now being printed by machine, upon a blank card, the moment they are delivered by the ticket office. The accompanying photograph illustrates a ticket-printing machine that is in use in a number of the large depots in Germany, and in England and the colonies. On the old method, the railroad company had to print and keep in stock a large number of tickets, and as these represented a great money value, they had to be stored and watched closely so as to avoid losses. Now the use of the machine overcomes all difficulties from this cause, for the tickets are printed only at the moment they are called for. When we consider that the machine shown in our photograph is able to hold 4,000 different printing plates, such as are needed for all the destinations, it will be evident that some ingenuity is needed to make up such an apparatus. The carriage which slides along the top is used for the printing, and a blank ticket is fed into a slot in it. Working the top handle causes one of the printing plates to rise up out of the bottom box or cylinder and enter the pointer, it being pressed upon the ticket so as to print it with the destination, price and other data, then another operator withdraws the ticket and hands it to the buyer. In the lower cylinder are numerous rows of plates all around it, and working a pedal causes an electric motor to bring the desired row to the top, at the same time working the name-bearing top cylinder, seen in the rear, by chain drive. The row of names is first brought under the pointer by proper rotation, then the carriage or printer is slid opposite the required name in that row. The carriage is now just over the right printing plate, so that working the handle causes the plate to rise, as we have seen, and allow of printing the ticket.

The cave farm is entered by means of a scow.



Mushrooms thrive in the humid cavern.

Emergency bridge used by Government surveyors.

Flexible-back hack-saw blade supporting a weight of 282 pounds.

A machine for printing railroad tickets as needed.

Farming in a Cave

A CAVE in the heart of the Ozark Mountains of Missouri is the unusual spot chosen for a farm by a retired citizen of St. Louis. While looking about for a farm in the western part of his home State, Mr. Robert Smith found an attractive 26-acre stretch, beneath part of which lay a large cave. Remembering the profitable use made of caves by the mushroom growers of southern France, he determined to test the productiveness of his acquisition.

Preparations for the experiment were simple. He first constructed a 25-foot flat-bottomed boat, for his only practicable access was by a small river running through the cave. Then while his neighbors were digging up weeds and clearing brushwood from their lands, Farmer Smith had to uproot and haul away the stalagmites and stalactites, the lime deposits left by the incessant dripping of water during many centuries. Except for a clayey substance, ocher, which covered part of the walls, the cavern floor was bare limestone, so that the final preliminary activity was to spread soil and manure over the ground.

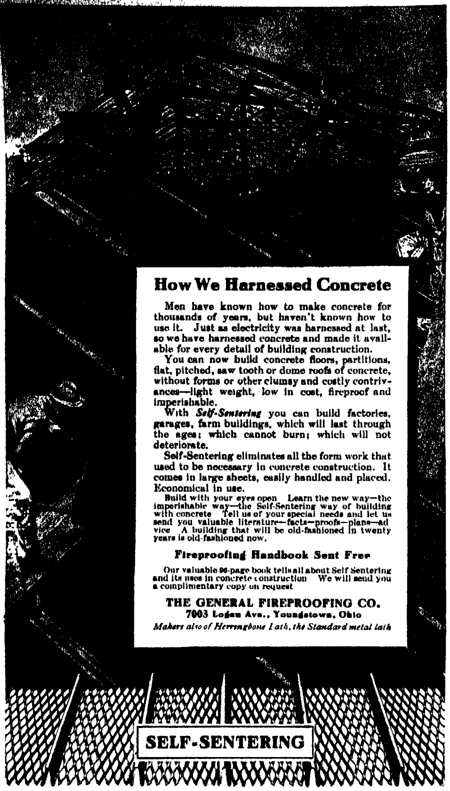
Mushrooms are peculiarly suitable for such a project as the cave farm. The spawn is secured in bricks, which are broken up and scattered over the floor surface From a single mulching, and with almost no care, the farmer can harvest a new crop of marketable mushrooms every day for three months. Allowing a brief period for the fungus to attain its full size, Mr. Smith can readily plant spawn three times each year. From this promising start, the subterranean agriculturist turned naturally to rhubarb and celery. These are planted above ground, and are later transplanted in the cave. The underground ripening causes an unusually rapid growth, the rhubarb gaining on the average an inch a day in length, and also gives the stalks a superior tenderness and a rich flavor

Besides the crops which the Missouri farmer is now producing regularly, the cave, with its fixed quantity of moisture and its temperature which never varies from 60 degrees, is better than a man-made cold storage house for keeping vegetables fresh indefinitely. So quickly did this condition become evident that all the farmers within a radius of 20 miles now store their sweet potatoes in the cave for periods as long as two years

A Remarkable Hack-saw Test

THE accompanying illustration shows a most interesting test of a hack saw in which a flexible-back blade supported two men, one weighing 147 pounds and the other 135 pounds, or a total of 282 pounds, without breaking. It is maintained that the best hack saw should have a soft flexible back with hard or tempered teeth. Often hack saws are operated at about as much as 150 strokes per minute, the operator forgetting that it is action and not speed that does the work. This is one of the most frequent abuses to which shop men subject a hack-saw blade.

The best speed for the blade is claimed to be from 40 to 60 strokes a minute, and no blade will stand higher speed without danger. The exact speed at which a blade should be run depends upon the material being cut. The harder the metal, the slower the speed should be. The operator should run the blade slow enough to feel the teeth take hold, as when filing If a cut must be made quickly, some sort of liquid on the blade such as a soap solution or lard oil should be used.



How We Harnessed Concrete

Men have known how to make concrete for thousands of years, but haven't known how to use it. Just as electricity was harnessed at last, so we have harnessed concrete and made it available for every detail of building construction.

You can now build concrete floors, partitions, flat, pitched, saw tooth or dome roofs of concrete, without forms or other clumsy and costly contrivances—light weight, low in cost, fireproof and imperishable.

With *Self-Sentering* you can build factories, garages, farm buildings, which will last through the ages; which cannot burn; which will not deteriorate.

Self-Sentering eliminates all the form work that used to be necessary in concrete construction. It comes in large sheets, easily handled and placed. Economical in use.

Build with your eyes open Learn the new way—the imperishable way—the Self-Sentering way of building with concrete Tell us of your special needs and let us send you valuable literature—facts—proofs—plans—advice A building that will be old-fashioned in twenty years is old-fashioned now.

Fireproofing Handbook Sent Free

Our valuable 96-page book tells all about Self Sentering and its uses in concrete construction We will send you a complimentary copy on request

Kinematographing the Matterhorn

(Concluded from page [illegible])

returned to the lower levels. The guides, although experienced to the conditions, also showed signs of distress, and the weight of the outfit was beginning to be felt. According to the regulations concerning the carriage of baggage upon Mont Blanc, the maximum load permitted per man is 10 kilogrammes (22 pounds): here there was about 50 per cent excess. As a matter of fact, two additional porters should have been requisitioned.

As the sun rose the party reached the abandoned club hut on the mountain. It is merely a box upon a shelf of rock. A second breakfast was partaken, and then it was decided to shed everything that could be spared. Practically all the food—for five—was left at the cache as well as other equipment. Slender supplies of a light wine were carried as there is no possible chance of quenching thirst above the *cabine*.

Beyond the hut comes the stiffest part of the climb: a toil up a 70-degree slope of ice and snow. The leading guide paused, shook his head, and emphasised the dangerous condition of the mountain. But Burlingham would not turn back. They cut steps every inch of the way, and this labor at such an altitude proved so extremely tiring that the advance was now exasperatingly slow. There was the danger that the summit would be reached too late to permit the descent to be made before darkness set in. When the "shoulder," which is a long steep ice slope, was reached, and a violent gale was encountered, the guides betrayed by their faces that they hesitated to go any farther. The air-current was whirling so viciously that it threatened to blow the whole party off the mountain. Moreover, the wind picked up small particles of frozen snow and hurled them against the men with blinding force. As it was, their faces were so filed by these driving granules that the skin was greatly irritated, and the discomfort was intense.

The arrangements provided for a respite of some 15 minutes at this point, but the situation became so alarming that the leading guide braced the party together, and told them to make a rush to the rocks above, where shelter might be obtained. The order was answered, and the kinematographing of this part of the journey conveys a striking impression of the dangers attending the climb. The operator set up his instrument, and one guide, to whom he was roped, used his body as a brace to support the tripod, while with his hands he clung to the operator's knees to prevent his being blown off his perch, and to frustrate any false movement, as the position was on a narrow ledge overlooking a drop of 3,500 feet. In fact, Burlingham became so absorbed in his work as to forget his perilous position, but this was brought home to him in a startling manner. He moved slightly to swing his camera round, and in so doing came to the edge of the precipice. Immediately a huge mass of snow and ice went overboard with a resounding crash, and had it not been for the strength of his assistant he must have gone too

The wind gave no signs of abating. The party had been climbing for 8½ hours, and were still far from the summit. One and all were blowing from their efforts. Zumtangwald took a look round and expressed his opinion that it would be inadvisable to go any farther. Burlingham, with the summit almost within his reach did not relish the prospect, and so, when he remarked "Very well, but if we go back we shall have to make another attempt" his companions decided to push a little farther ahead, and if the conditions did not improve, to retreat. They had no desire to repeat the ascent as its dangers and difficulties had been revealed only too potently.

Curiously enough, after another fifteen minutes' hard toiling, a point was gained above the air current where virtual calm prevailed. Above the "shoulder" there are several permanent cables, knotted rope and wire to assist ascent. By their aid faster progress was made. Gaining the upper level they passed the spot where the four

Only 1 oil in 9 is correct for *your* car

That is conservative.

There are two vital factors in automobile motor lubrication. One is the oil's *quality*. The other is the fitness of the oil's *body* for your type of motor.

There are also many variations in the *body* of oils.

Only one is correct for *your* motor.

There are also many variations in *quality*. But under the heat of service in your motor, only one *quality* will show maximum lubricating efficiency.

What if your oil is below the highest *quality* or incorrect in *body*?

Loss of power or undue friction, or both, must result. Repair bills follow.

Consumption of gasoline and oil mounts up.

Two motor demands

You may "want" correct lubrication. But you will seldom get it by chance.

It is of the utmost importance that you find the oil whose *body* suits your motor and whose *quality* offers the highest protection after the oil has been distributed.

It is now generally known that oil of correct body for your car can be determined only by detailed motor analysis—backed by scientific lubricating experience.

How friction hides

We are sometimes asked why incorrect lubrication does not always show up quickly in a motor.

That is an interesting question.

Some years ago motor parts were more exposed. Cars were often under-powered. Noise, overheating and loss of power gave the motorist timely warnings to investigate his lubrication.

But today most motors are amply powered and are largely closed in. Loss of power may not be noticed. Sound is deadened beneath metal jackets. Parts are frequently out of sight and hearing.

It is much like smothering an alarm-clock gong under a pillow.

The *noises* of friction are now partly smothered. But the *friction* still exists.

There is only one safeguard against undue friction—*correct lubrication.*

The solution

As a fundamental step in producing the oils specified in the Chart below we analyzed the motors of every make of automobile. We found widely varying conditions.

Correct lubrication for every type of motor demanded several grades of oil.

Keeping before us the special requirements of gasoline engine lubrication, we manufactured these grades from selected crude stocks.

In our Lubricating Chart we then specified the correct grade of Gargoyle Mobiloil for each car. Every year by fresh analyses and demonstration, this Chart is brought up to date to cover the models for that year.

This Chart, printed in *part* below, for a number of years has been a standard guide to correct lubrication. Our *complete* Chart will be mailed you on request.

Make a note of the grade of Gargoyle Mobiloil specified for your car. Make sure that you secure it—buying preferably in the original barrels, half-barrels and sealed five-gallon and one-gallon cans, marked with the red Gargoyle.

Then there can be no doubt that your oil will be scientifically correct for your car in both *body* and *quality*. You will use the "one" oil essential to the longest life of your car and the greatest pleasure in motoring.

On request we will mail a pamphlet on the Lubrication of Automobile Engines. It describes in detail the common engine troubles and gives their causes and remedies.

The various grades of Gargoyle Mobiloils, purified to remove free carbon, are:

Gargoyle Mobiloil "A"
Gargoyle Mobiloil "B"
Gargoyle Mobiloil "E"
Gargoyle Mobiloil "Arctic"

They can be secured from reliable garages, automobile supply houses, hardware stores, and others who supply lubricants.

For information, kindly address any inquiry to our nearest office.

A guide to correct Automobile lubrication

Explanation: In the schedule, the letter opposite the car indicates the grade of Gargoyle Mobiloil that should be used. For example, "A" means "Gargoyle Mobiloil A" "Arc" means "Gargoyle Mobiloil Arctic." For all electric vehicles use Gargoyle Mobiloil "A." The recommendations cover both pleasure and commercial vehicles unless otherwise noted.

New Speed in Billing

This mechanism saves your bookkeeper's time. It foots your bills *as fast as they are typed*

HERE is the latest Remington achievement in time-saving—an easy-running typewriter with a head for figures.

It relieves your bookkeeper of school-boy addition and subtraction. It frees him for more important duties. It compels accuracy.

* * * *

Suppose you have the machine before you

Press the numeral keys.

Look!

Each type stroke does double duty. *You will see the amounts not only typed, but added* The two acts are simultaneous.

Your discounts are subtracted mechanically with equal ease

Without a single interruption for addition or subtraction your bills are ready to mail

From this time forward stopping to foot bills and statements, or check totals will be sheer waste of clerical time

Your totals once entered are as correct as though certified by an expert accountant.

* * * *

After turning out a batch of bills your typist may wish to typewrite letters

Very well! Switch a lever She has a complete, fully-equipped Remington Typewriter.

Every business purpose which calls for writing and adding on the same page, calls for this latest Remington time-saver.

* * * *

If you have a large business you can use several of these time-savers If you have a small business *one* will effect a quick saving in billing and charging.

The initial cost is soon wiped out. The more work you give the Remington Adding and Subtracting Typewriter the quicker it pays for itself

Your present typist can start using it tomorrow By night she will be saving you time and money

* * * *

The Remington Adding and Subtracting Typewriter is now used constantly by the United States Sub-Treasury, Banks, Railroads, Life Insurance Companies, retailers, manufacturers and many other businesses, large and small.

It is good for many years of "heavy days" work.

* * * *

Sooner or later you will write and foot your bills simultaneously.

You can't begin too soon. Delay simply means more time-waste and error-risk in your office.

Write today to our New York office for booklet, "The New Remington Idea," which describes this remarkable machine in detail.

* * * *

The Remington Adding and Subtracting Typewriter can be had in any of the Remington Models shown below.

Each is a member of the famous Remington family.

Each is a complete easy-running typewriter, plus the adding and subtracting feature.

Each is designed and built so as to insure maximum durability.

Each has distinctive features designed to meet individual requirements.

Write today for booklet, "The New Remington Idea."

"AMERICAN"
No. 3 Patented

The "AMERICAN" is the only machine on the market (barring none) that sharpens, hones and strops razors, sharpens all kinds safety razor blades, scissors, clippers, pocket knives, surgical instruments, etc. No previous experience required.

American Sharpening Machine Co. (Inc.) Dept. B. 504 W. Washington St. Chicago

members of the Whymper party were lost and then strode rapidly forward over the snow and ice to the summit ridge. Warily walking along this narrow causeway they at last reached the topmost point, or rather the highest spot which could be trodden in safety, because, as a matter of fact, the snow had been blown by the north wind over the summit to form a big cornice, a fall through which would have landed one into the valley of Breuil 8,000 feet below

The weather was perfect except for the violent wind The camera was set up, and with the party holding the operator securely, magnificent panoramas from an elevation of 14,705 feet were obtained The work of Burlingham was followed with intense interest through the hotel telescopes, by those in Zermatt below, the arrival of the party at the summit having been awaited with suppressed excitement.

Owing to the time occupied in the ascent, work at the summit had to be hurried, and then, the equipment packed away, the descent commenced. Unfortunately this was more difficult than the upward climb, as the Whymper party encountered its tragedy while going down, while in this instance the presence of the wind which was obliterating the ascending tracks, constituted an additional source of anxiety. Careful haste was urgent as time was slipping by. The first part of the journey was completed without incident, but when the "shoulder" was gained extreme care had to be exercised. The weight of the apparatus now became revealed in a striking manner, for it hampered the free movement of the fatigued porters very appreciably Burlingham, not being familiar with the mountain had one thrill. Descending backward over a projecting rock with a sheer drop of hundreds of feet into the abyss is not an easy acrobatic achievement, and although the operator is an experienced climber, he once got into a serious difficulty He was going down hand over hand, but presently failed to find a finger hold among the crags. He was dangling over a precipice unable to move forward or backward. He called out desperately to one of the porters. The latter, realizing his perilous situation, hurriedly descended hand over hand, keeping the rope taut, and, at last grasping the helpless operator, hauled him up to a point whence descent might be safely effected.

It was six in the evening, and the party were on dangerous ice banks sloping upward at 80 degrees. Snow began to fall, and it seemed as if a blizzard were about to burst. The leading guide apprehensively urged the party to faster movements or they would all be overwhelmed. While descent thereupon was accelerated, no long chances were taken in the bad places, although it was only due to the expert assistance available that no accidents occurred. When at last the club hut was gained it was almost dark, and, as a pall of clouds shrouded the mountain below them they realized that the last pull to the *Cabine* below would be fraught with extreme risk They were too tired to eat the food they had left in the hut in the morning, and without any untoward delay, they continued their downward way over the ragged crags. Presently they caught sight of the lights in the *cabine*, and at 9·15 entered its welcome door, after having been climbing continuously for 18¾ hours. At Zermatt the crowds had grown anxious. The snow-fall on the peak had been observed, and as darkness had overtaken the expedition, became apprehensive of its safety.

When the party, practically played out, entered Zermatt, after having been absent for nearly three days, the guides acknowledged that it was the most difficult enterprise with which they had been associated in connection with the Matterhorn. As for the operator, Frederick Burlingham, he was completely satisfied. He had kinematographed the Matterhorn from Zermatt to its crest upon 1,500 feet of film, which upon subsequent development proved perfect in all its essential qualities, and conveys to the masses some of the finest impressions of the Matterhorn, which ever have been secured. The suc-

[illegible] of this expedition prompted Burlingham to repeat his performance upon Mont Blanc, but the highest peak in Europe being easier to climb than the Matterhorn, greater interest is attached to the latter. His movies thereof appeal to mountaineers and are possessed of distinct educational value, while the achievement is one of the most brilliant in the history of kinematography.

The 200 Horse-power Curtiss Motor for the Rodman Wanamaker Transatlantic Flyer

THE 200 horse-power aeronautical motor for the Rodman Wanamaker transatlantic flyer was given a five-hour run at moderate speed recently, and is said to have behaved well. As the motor had had but little limbering under shop power it has been thought advisable to keep the speed below 1,100 revolutions per minute for the first few days, but even at that speed the nine and one half foot experimental propeller shows a static thrust of more than 800 pounds.

The motor is of the Curtiss V-type, eight cylinders, with a bore and stroke of five by seven inches. The cylinders are individual, with welded water jackets of non-corrosive Monel metal. Each cylinder has four tungsten steel valves two and one fourth inches in diameter with seven sixteenths inch lift. All thirty-two valves are operated from a single camshaft. The cylinders are held down to the crankcase by tubular studs from the heads with extension bolts passing through main bearing caps. All the outside bearings are self-lubricated with graphite.

The crankcase is composed of two aluminium castings, thoroughly bridged. The crankshaft is four feet long, two and one fourth inches diameter, and is drilled with an oil duct one and one sixteenth inches diameter. It is made of imported Krupp steel. The connecting rods are I-type forgings with large bearings and oil ducts leading to the piston pins.

Water is circulated by large centrifugal pumps with double outlets. The cylinder heads and valve seats are water cooled, and the exhaust valve stems are water cooled for almost their entire length.

Three rotary gear pumps take care of the lubricating system. One large pump drives the oil under high pressure to every bearing through the main shaft, cam shaft and connecting rods; while two smaller pumps keep the lower half of the case drained. No splash system is employed, the idea being to eliminate the waste of oil and danger of flooding the cylinders should the machine assume an unusual angle.

The gasoline intake manifolds are two and one half inches in diameter and are water jacketed. Ignition at present is by two-spark magneto, but this may be replaced later by two single spark instruments of the half-speed induction type.

The Next Road Congress

THE fourth American Road Congress, and the convention of the American Highway, all its affiliated organizations, and the American Automobile Association, have been scheduled for Atlanta, Ga., during the week beginning November 9th, 1914.

This announcement, which has been awaited by the various organizations working for better roads, was made in Washington by J. E. Pennybacker, secretary of the American Road Congress. The convention city was selected some time ago, but the date was left open until Mr. Pennybacker made definite announcement in Washington.

It was also announced that in addition to the road organizations, committees of the American Bar Association and the American Bankers' Association would work in conjunction with the American Highway Association to make the fourth road congress crystallize the movement for more uniform road laws and a better system of financing road improvement throughout the country.

This will be the first meeting of the American Road Congress in the South, and is a recognition of the great energy and [illegible] that has been made in that sec-

The Spirit of Service

WHEN the land is storm-swept, when trains are stalled and roads are blocked, the telephone trouble-hunter with snow shoes and climbers makes his lonely fight to keep the wire highways open.

These men can be trusted to face hardship and danger, because they realize that snow-bound farms, homes and cities must be kept in touch with the world.

This same spirit of service animates the whole Bell telephone system. The linemen show it when they carry the wires across mountains and wilderness. It is found in the girl at the switch-board who sticks to her post despite fire or flood. It inspires the leaders of the telephone forces, who are finally responsible to the public for good service.

This spirit of service is found in the recent rearrangement of the telephone business to conform with present public policy, without recourse to courts.

The Bell System has grown to be one of the largest corporations in the country, in response to the telephone needs of the public, and must keep up with increasing demands.

However large it may become, this corporation will always be responsive to the needs of the people, because it is animated by the spirit of service. It has shown that men and women, co-operating for a great purpose, may be as good citizens collectively as individually.

When Was Gen. Juarez President of Mexico?

Our neighbors across the Rio Grande have been monopolizing the front pages of the newspapers for some time now. But with all the publicity they have had, most of us know very little about Mexico.

Except that Cortez was an early settler who fooled the immigration officers by burning his ships, and then gave Montezuma a wallop below the belt when the latter wasn't looking.

Since then Mexico has produced a number of notable figures. We mention Juarez because he was making history down there at the same time that Richmond Straight Cuts were marking off an epoch up here.

The fickleness of popular favor has been proved a thousand times: Richmond Straight Cuts stand as one of the exceptions. The Cigarette that won fame forty-two years ago, still remains the best of all Virginia Cigarettes. It has a quality that cannot be forgotten.

Besides the regular package of 20, these cigarettes are also packed in attractive tin boxes, convenient for den, office or traveling, 50 for 40c; 100 for 75c. These larger packages will be sent prepaid on receipt of price, if your dealer cannot supply them.

tion in the movement for improved roads. In 1913, about $40,000,000 was expended by southern States on their public roads, in addition to the labor of thousands of State convicts. Georgia alone had her entire convict force, numbering nearly 5,000, engaged in road construction.

The tremendous importance of guarding against extravagance in road expenditures is shown by the fact that while a recent report of the Census Bureau indicates that the total bonded debt of the forty-eight States last year was $419,157,000, in the single year of 1912 the States spent about $142,000,000 on roads. The total indebtedness had been accumulating for years, and yet in one year an amount equal to about one third was spent on roads. This subject will be dealt with exhaustively at the coming congress

One of the principal results hoped for by the management of the congress will be the establishment of State highway departments in the six southern States which have thus far failed to adopt the plan of State supervision, namely Georgia, South Carolina, Florida, Tennessee, Mississippi, and Texas. Aside from these six States only Indiana and Montana have failed to establish State highway departments for educational or constructive work.

The 1913 American Road Congress was held in Detroit, Mich., with an attendance of about 4,000, representing forty-four States, and with a vast array of exhibits, in which the United States Government, many of the States, educational institutions, and over one hundred manufacturers participated. This year it is expected that the congress will have an attendance well over 5,000, and in preparation for the exposition to be held in connection with the congress, under the direction of Charles P. Light, business manager, the city is preparing to erect temporary structures covering the entire street space on both sides of the auditorium, and to close to traffic, during the entire congress, a viaduct extending two blocks. Steps are now being taken toward securing favorable railroad rates and committees are being formed to provide for the comfort and entertainment of the congress which will include many of the most distinguished men of the nation.

Stresses in Railroad Tracks

A SUB-COMMITTEE has been appointed by the American Society of Civil Engineers to co-operate with a similar committee of the American Railway Engineering Association to conduct tests on stresses in tracks. The members of this committee are as follows:

A. N. Talbot, Chairman; A. S. Baldwin, J. B. Berry, G. H. Bremner, John Brunner, W. J. Burton, Charles S. Churchill, W. C. Cushing, E. Gerber, George W. Kittredge, William McNab, C. J. Ray, F. E. Turneaure, J. E. Willoughby.

The Railway Engineering Association appointed a special committee consisting of the men named in the above and in addition thereto the following:

W. M. Dawley, Vice-chairman; H. E. Hale, Dr. P. H. Dudley, J. B. Jenkins, P. M. LaBach.

The first meeting of this committee was held at the Congress Hotel, Chicago, during the annual meeting of the Railway Engineering Association, March 17th to 20th, 1914.

A sum of $10,000 has been subscribed by the U. S. Steel Corporation to defray the expenses of this investigation, and this sum has been supplemented with $2,000 by the American Society of Civil Engineers.

Murder of an American Botanist

A MELANCHOLY postscript must be added to the note published in the SCIENTIFIC AMERICAN of December 13th, 1913, describing the unique expedition to Amboina, Dutch East Indies, undertaken by Dr. Charles Budd Robinson of the Philippine Bureau of Science. Press dispatches report that the explorer was murdered by natives soon after his arrival in the island. Dr. Robinson was a Canadian by birth, but was partly educated in the United States, and was at one time on the staff of the New York Botanical Garden.

Maxwell "25-4"
5 Passenger Touring Car

Stripped of All Adjectives and Advertising Verbiage This $750 Maxwell Is

A CAR DESIGNED FOR THOSE discriminating buyers who yet must consider the pocketbook—or who, able to pay more, don't choose to—and who want a light family touring car of ample power to go anywhere; of reliability that guarantees a pleasurable return sans road troubles of any kind.

A CAR THAT WILL PERFORM; but also a car that looks the part; a car for the man who considers his automobile an everyday necessity and who counts the cost. A car that is economical in cost of upkeep—gasoline, oil and tire consumption.

YOU HAVE OFTEN SAID that you would be willing to pay a little more for a car that looked a lot better.

THIS IS THE CAR. It has been designed from your standpoint—for thousands of others have expressed the same desire you expressed.

KNOWING THE NEED—the demand—we have designed to meet it.

AND IT'S MADE JUST AS WELL as it's designed. Every ounce of metal that goes into it has been specified by our chief metallurgist, after the most exhaustive analyses and tests to determine the kind of metal—and alloy and heat treatment that would best meet the requirements and perform the functions of that particular part.

BETTER MATERIAL does not enter into the construction of any car on earth at any price; for here is the best the science of metallurgy and automobile construction knows.

THE MAXWELL MOTOR COMPANY offers this car without a mental reservation—and every dollar we have, and our reputation, stand back of it, to guarantee every owner satisfaction.

How the American Museum giant model of a flea was made.

A Huge Model of the Flea

NOT the least striking and instructive of the thousands of exhibits in the American Museum of Natural History are the large models of common insects, which have attracted the wondering attention of thousands. Is the mosquito really so fierce an animal? Is the fly so horrible? Who made these models? How did he do it? Probably every one of the visitors to the American Museum of Natural History who has seen these wonderful models has asked himself these questions. Not one in ten thousand realizes that the models are works of art in their own particular way, and that in the whole world there are probably not more than two or three artists who are sufficiently skilled in entomology, and whose hands are sufficiently trained and dexterous to produce this work. The American Museum of Natural History is fortunate in having secured in Mr. Ignaz Matausch one of these very few and highly exceptional scientific artists to prepare its models. It may be safely said that Mr. Matausch is probably the only man on this side of the Atlantic Ocean capable of executing such work.

Mr. Matausch's latest creation is a flea magnified in wax 1,728,000 times the size of the insect in bulk. In other words, 1,728,000 actual fleas could be packed into his model if it were hollow. Although the model excites admiration because of the skillful manner in which it was prepared, it tells nothing of the painstaking preliminary studies which were necessary before work could be commenced.

Strange as it may seem, no picture has ever been made of the living flea. The insect as it is pictured in text books is a dead insect. To the uninformed it seems a very trivial matter whether a flea is magnified in wax alive or dead The entomologist knows better He knows that the segments telescope after death because of the shrinkage of the internal organs.

Accordingly Mr. Matausch began by making an entirely new external anatomical study of the flea Numerous specimens of the insect were observed under the microscope, so far as possible in the living condition When all that could be learned had been thus acquired and drawings had been carefully made to scale, the appendages were separated from the body. While even the dissection of the larger members is a test for any skilled hand, what shall be said of bristles and hairs so minute that the point of the finest dissecting needle is enormously larger than the part to be separated? The task is not unlike that of severing a human hair from the scalp with the aid of a crowbar Literally, dozens of drawings had to be made to scale; each part had to be minutely measured.

After all this painstaking preliminary work models of each part were prepared of the desired size in modeling clay and forms made in plaster of Paris. From these plaster forms hollow models of the parts were made in a properly colored wax composition. The hollows in the wax parts served for the wires in the legs and other supports and connections which give stability to the whole. The finishing of the details of the structure then followed. Bristles and hairs were prepared from German silver wire and placed at the points revealed in the drawings by microscopic study. The whole model was thereupon colored, assembled and treated with a coat of lacquer to preserve it.

Those who look at this flea in the American Museum of Natural History will see far more than even the eye of a trained entomologist sees with the aid of a powerful microscope. So small were some of the hairs (for example, the two that project upward from the mouth parts of the insects) that days of patient observation were required before at last their point of attachment could be seen in a particularly favorable moment.

Perhaps that organ of the enlarged insect which will attract most attention is the biting mechanism As pointed out by Carroll Fox in a bulletin of the United States Public Health Service on "The Rat and Its Relation to the Public Health," the flea does his biting with a beak which consists of three inner and two outer parts The middle one of the inner parts terminates in a piercing point; the others in saw-like endings. They are close together and constitute the salivary and sucking ducts, through which the saliva is forced into the wound and blood extracted The two outer parts form a protecting case at rest and are not inserted, but serve as a guide, doubling back in the act of biting. They probably assist the piercing parts from the wounds In front of the beak are two plate-like members, ending in a sharp edge; after the piercing parts are inserted deep enough, they help in enlarging the wound.

It is with this beak that the flea sucks up blood. When the bubonic plague infection prevails, it is the bite of the flea that transmits the germs from rat to man, and from man to man.

For Shingles Alone, 750 million feet of timber is cut in that part of the State of Washington which lies west of the Cascades.

The Lesson of a Ferryboat Collision

THE recent collision in the North River between a Lackawanna Railroad ferryboat and a freight-car float, which occurred in broad daylight, draws attention to a danger in ferryboat navigation on this waterway, which only needed such an accident as this to show how disastrous its results may be. We refer to the practice, altogether too common, of navigating two ferryboats which are steaming in the same direction, with the second boat in close proximity to the one ahead The danger lies in the fact that the leading boat obstructs the view of the pilot of the second boat to such an extent that, when the leading boat changes course, the following boat may suddenly find herself in close proximity to a craft which was shut out from view by the boat ahead. In the accident referred to, the "Ithaca" of the Lackawanna Line left her dock at the foot of Barclay Street at about the same moment as the Erie ferryboat "Goshen" left her berth at the foot of Chambers Street. The "Ithaca" was steaming on the port quarter of the "Goshen," and so close that a biscuit could be tossed from one boat to the other. Then, upon the "Goshen" turning to port and clearing the bow of the "Ithaca," the latter boat found herself only a few hundred feet from a Jersey Central float laden with ten freight cars. There was no room to maneuver, and the float crashed into the ferryboat, crushing and killing three of the people in the cabin. Those who make constant use of the ferryboats in the North and East Rivers will understand from the above how this accident happened, for they will have often noticed that one boat will follow another in such close proximity that its view ahead is very much obscured, particularly as regards the observing of such low-lying craft as a float or tugboat. The danger is so real that we think it would be advisable to pass a law requiring ferryboats to reduce speed, when in close proximity to a boat ahead, sufficiently to enable them to be maneuvered in any sudden emergency that may arise

Stresses in Railroad Tracks

WE are greatly interested to note that a sub-committee has been appointed by the American Society of Civil Engineers to co-operate with a similar committee of the American Railway Engineering Association to conduct tests on stresses in railroad tracks A sum of $10,000 has been subscribed by the United States Steel Corporation to pay the expenses of this investigation, and we understand that this sum has been supplemented with $2,000 by the American Society of Civil Engineers Doubtless, as the importance of this investigation is realized, other contributions will be forthcoming, and a sufficient sum will be available to render this investigation as comprehensive and searching as it must be to secure adequate results

So far as we know, except for limited experimental work done by individual engineers, there has been no attempt to determine with scientific accuracy the amount and kind of stresses to which modern railroad track, including every element from the grade line through the ballast, ties, and rail, is exposed by the action of moving trains Considering that the track lies at the foundation of successful railroad transportation it is surprising that it was not subjected periodically to careful and exhaustive physical tests, to determine the nature and extent of the stresses to which every part of it is subjected under the various conditions which exist both in track and traffic. These things are known, of course, in a general way. It is understood, for instance, that a soft, yielding spot in the subgrade will cause the rail to be subjected to bending stresses far greater than those which occur under normal conditions. We know that the same results will follow if two or three adjoining ties are badly tamped while those beyond them on either side are fully tamped. We know that during the frost of the late winter, the heat of the rays of the sun, especially under certain atmospheric conditions, may soften the roadbed where the sun strikes full upon it, leaving the adjoining stretch of track, which may be under the shadow of a bridge or a building, in a thoroughly frozen condition—a situation which, as in the case of the accident on the New York Central at Woodlawn several years ago, no doubt greatly contributes to derailments But the engineer would like to know how great and how sudden may be the change in track conditions due to such juxtaposition of sunlight and shadow.

These questions and many others will now be determined by this Committee, which doubtless will take up the subject of tie plates, screw spikes, track spikes, the best form of rail-joint fastenings and many another subject upon which, even at this late hour, much valuable light is needed. The Safety First movement is very much to the front in these days, and we do not know of any contribution to safety which can exceed in importance the work of this committee, the list of whose membership was given in our last issue.

The Ship and Its Lifeboats

THE International Conference on Safety of Life at Sea, whose meetings extended from November 12th, 1913, to January 20th of this year, has published a convention embodying the results of its deliberations, which will be ratified on the last day of this year, and will come into force on July 1st, 1915. We hope to give an early and more extended reference to this convention; but for the present we direct attention to the more important sections, dealing first with the construction of ships and second with the provision of lifeboats. Broadly speaking, it must be admitted that the work of the conference, representing as it does the conscientious and earnest labor of some of the ablest and most experienced minds connected with the construction, control and operation of ships, is certain to exercise a decided influence on the future design and operation of steamships

The conference dealt through its five sub-committees with the following subjects: Safety of Navigation, Safety of Construction, Wireless Telegraphy, Life-saving Appliances, and Certificates. As was to be expected, the various sub-committees found no difficulty in reaching practically unanimous conclusions on the questions of Safety of Navigation, Wireless Telegraphy, and Certificates The greatest division of opinion developed in the sub-committee on Safety of Construction and to a less degree in that on Life-saving Appliances; and it is to these two subjects, which to our mind are strictly interdependent, that we confine ourselves in the present discussion.

It developed during the inquiry into the "Titanic" disaster, held under Lord Mersey, that in the years preceding that disaster, the question had been raised and rather fully debated, as to whether the number of lifeboats which a passenger ship was required to carry should not have a certain, definite relation to the degree of safety against sinking which had been secured in the construction of the ship itself The "Titanic," which failed so completely in the hour of extreme trial, both as regards the unsinkable qualities of the ship itself and as regards the provision of lifeboats, had been built, as was shown at the time, in strict conformity to the requirements of the Board of Trade. The Board of Trade rules demanded that the spacing and height of the bulkheads of the "Titanic" should be such that she could fill two adjoining compartments without sinking below a draft that would bring the water level within a foot or two of her bulkhead deck. They required, also, that she should provide lifeboat accommodation for about one third of those on board. Both of these conditions were fulfilled The "Titanic," however, was so badly ruptured that at least five of her compartments were opened to the sea—and she went down; furthermore, the boats available carried only about a thousand passengers, and over fifteen hundred of her complement were lost with the ship.

The rules adopted by the London Convention require that the height and spacing of the bulkheads shall be such that three of the largest compartments of a passenger ship of the type of the "Titanic" may be filled without endangering the ship, and there are other provisions as to height of bulkheads and the watertightness of the bulkhead decks, which if ratified and followed, will produce a much safer ship than those built under the existing laws. Whether the sub-committee on construction has gone far enough in the direction of safety is a question open to debate; we are inclined to think that it might have made its rules more stringent without imposing any serious burden of cost upon the shipping companies.

The recommendations of the sub-committee on Life-saving Appliances are so sweeping that we cannot help but feel that the committee was unduly influenced by popular clamor and by the well-meant, but ill-digested opinions of the popular press. This committee calls for the provision of lifeboats for every soul on board; and this, in the case of the largest trans-Atlantic liners, 900 to 950 feet in length, means that their top decks must be lumbered up with a mass of lifeboats so large that in the event of emergency it is improbable that, even under favorable conditions, they could all be safely loaded and got away from a sinking ship.

There is no doubt that this provision was influenced largely by recognition of the fact that, however perfect the sub-division of a big ship may be, there will always be the possibility that a serious fire will necessitate everybody on board taking to the boats. As against this view, it should be noted that the Committee on Construction calls for the provision of fireproof walls, or bulkheads, running across the passenger accommodations at stated intervals, which must be capable of confining a fire to that section in which it originates. If this provision is adequately carried out, we believe that the occurrence of a conflagration that would drive everyone to the boats would be a very remote contingency. To sum up, we consider that it is entirely within the resources and skill of the ship designer and ship builder to produce a ship which shall be at once practically unsinkable and practically fireproof. If this be true, such a ship need carry only a limited number of boats, sufficient, let us say, for the ordinary uses of docking, and for assisting in the transfer of passengers to the rescuing ships which have been called to the vicinity by wireless.

The SCIENTIFIC AMERICAN, from the very day of the "Titanic" catastrophe, has laid down the principle that the proper method of safeguarding the lives of passengers at sea is to make every ship so far unsinkable, that, in the event of serious disaster, it will act as its own lifeboat, and take care of its passengers until they can be either brought into port or transferred at sea to other ships. The mere logic of the thing teaches us that the only safe and thoroughly reliable lifeboat is the ship itself. Can it be denied that the mass of small craft, open boats, motor boats, life rafts and what not, that encumber the top deck of an Atlantic liner are, in a sense, a confession of failure—an admission on the part of the architect and ship owner that although they have succeeded in making the ship big, fast and luxurious, they have not succeeded in making her safe? We note that our contemporary, the *Engineer* of London, is now taking this sensible view of the case. "Boats," it says, "are a continual rebuke to the shipbuilder and the ship commander; for they remind him that his skill is still so far wanting that his vessel is still liable to accident on the high sea It must be the object of both men to remove that rebuke."

However, the London Conference calls for boats for all. We understand that one of the big 900-foot ships that will make her maiden trip to New York during the coming summer will enter port with no less than ninety-two lifeboats crowded upon its top deck. Well, if it must be so, we can only express the hope that the gradual appreciation of the fact that a big ship can be made practically unsinkable, will lead to the reduction of this unnecessary top hamper, and that ultimately a few large and well found motor boats will take their place.

Delta Rays

THE name δ ray was given by J. J. Thomson in 1905 to the slow electrons emitted by polonium and which has previously masked the positive charge of the α rays. A little after Rutherford discovered a similar emission for radium and showed that it is not exclusive to the source of the α rays, but is produced by all bodies struck by these rays.

Recently Gargan and Bumstead have shown that certain rays of a sheaf of δ rays are endowed with greater velocities than those which have hitherto been measured; a retarding potential difference of 1,700 volts does not stop them. In a recent memoir Bumstead arrives at the following results. When α rays strike a metal they cause the emission of electrons of which the velocities vary progressively from a very low figure to about three thousand million centimeters per second. He proposes to call all these δ rays. At the same time there is an emission of positive ions from a metal placed in a high vacuum and bombarded by α rays: these ions seem to come from gas absorbed into the surface of the metal.

When the δ rays encounter a solid, they produce an emission of slow electrons which Bumstead calls tertiary electrons. Their number is much greater than that of the δ rays which produce them.

Engineering

The First Railroad in Iceland.—According to a dispatch from Copenhagen, a railroad 60 miles in length is to be built in Iceland. At present there is not a mile of railroad in the whole of that island; indeed, it is devoid even of good roads, as we understand the term in this country. Such roads as exist in the island are mere bridle paths.

Wood Spring Tires.—An interesting experiment has been made in England with wood spring tires which have been fitted to a one-ton motor truck. The experiment has been satisfactory as far as it has gone, as the wood blocks do not appear to have been deformed and show little signs of wear. *The Engineer* states that these results were obtained after a run of over 3,000 miles.

The Coal Fields of the Antarctic.—Prof. Edgeworth Davis, lecturing before the Royal Geographical Society, stated that he did not believe the world as yet realized the scientific as well as the commercial importance of the great coal fields which Sir Ernest Shackleton discovered at the head of the Beardmore Glacier, and which in a small strip contain probably as much coal as exists in all the unworked coal fields of Great Britain.

Tunnels Versus Bridges.—The idea that a tunnel can be compared favorably with a bridge, in point of its capacity for a given cost, is erroneous and unfortunately is very widespread. A bridge such as that proposed across the North River would accommodate six to eight times as much traffic as could be sent through a tunnel; in other words, the cost for a given amount of traffic would be very much greater for the tunnel than for the bridge.

The Father of the Dreadnought.—To the lately deceased Cuniberti, Major-General of the Italian Naval Engineering Staff, is due the credit of having first suggested the modern dreadnought. It was he, also, who suggested the modern type of scout, and he was one of the first to study the question of the application of liquid fuel to marine boilers. It was his influence which led to the adoption of this fuel in the Italian torpedo boat service.

Gatun Lock as a Dry Dock.—One of the locks of the Panama Canal at Gatun has been put to the novel use of serving as a dry dock for the overhauling of five of the submarines, T-1 to T-5, which have been stationed at the Atlantic entrance to the canal since December 12th last. The lock chambers are arranged in pairs, and it is therefore possible to use one of them as a dry dock without interfering with the passage of vessels through the other.

Panama Grows More Healthy.—The last report of the Department of Sanitation at Panama for the year 1913 shows that for the Isthmian Canal Commission and the Panama Railroad Company, out of 56,054 employees there were 473 deaths, giving a rate per 1,000 of 8.35. This is the lowest rate recorded since the United States took possession of the Canal Zone. The next lowest was in the previous year, 1912, when the rate per 1,000 was 9.18. The highest, 41.73, occurred in the year 1906.

A Transformed Tank Ship.—A sailing tank ship, "Jules Henri" of Marseilles, has recently been transformed into a motor tank ship at Wilton's shipyards in Rotterdam The ship, which originally was 76 meters long, was cut in half after the masts had been removed, and a new section 17 meters long was built at the break. Two Diesel motors each of 500 horse-power were then installed. The transformed motor tank ship is now 93 meters long by 12.25 meters wide, and has a capacity of 3,000 tons of oil. After a first voyage to the Black Sea the ship will be employed regularly between Europe and America.

Two of the Most Recent Types of Oerlikon Steam Turbines are now running in the central electric station of Stockholm, these being of 10,000 horse-power size. Turbine and dynamo make up a compact group, and the turbines are of a new design, which is claimed to have a number of advantages, one of these being a low steam consumption of 7.9 pounds per horse-power hour. The turbines operate at 3,000 r.p.m. standard speed. Such turbines are made up as usual of blade wheels each in a separate steam chamber, but the combination of speeds and pressures within the turbine is based on a somewhat novel theoretical design.

Concrete Poles Withstood the Storm.—The great strength of reinforced concrete telegraph poles was proved to a demonstration during the violent storms of this winter. The Pennsylvania Railroad Company states that this was shown in the case of their telegraph lines, where a large number of reinforced concrete poles were exposed to the recent heavy storm, which practically isolated New York city. Though many of the wooden poles were broken down by the wind, in no case did a reinforced concrete pole fall, and this in spite of the fact that so severe was the stress that the wooden cross arms upon some of these poles were broken. They are made of Portland cement, reinforced with steel rods. They have the further advantages, in addition to their strength, that they do not rot at the ground, and that they never rust as do the steel poles.

Electricity

Marconi's Radiotelephone Experiments.—According to press dispatches, Mr. William Marconi is meeting with considerable success in his wireless telephone experiments, and is confident that transatlantic radiotelephony will be an accomplished fact at some not far distant day. Mr. Marconi has been conducting experiments from the Duke of Abruzzi's flagship, the "Regina Elena," off Agosta, Sicily, and has succeeded in maintaining radiotelephonic communication with ships from 18 to 43 miles distant. In connection with his receivers Mr. Marconi has been using phonographic recorders and has succeeded in recording telegraph signals from Clifden, nearly 2,000 miles distant, and from Canada, 4,000 miles away.

Copper Wire can now be made by an electric bath process, which is said to be very successful. A fine copper wire is connected to one pole of a battery, and is made to traverse a bath of sulphate of copper such as is ordinarily used for electro-plating, with a small amount of sulphuric acid added. In the bath is placed a heavy copper plate as the second electrode. The fine wire acts as a core and is covered with the deposited copper. Then after passing through a washing tank it is dried and runs upon a reel on which it is hardened by means of friction. The wire then returns to the plating bath and takes another layer, and so on until it has attained the required thickness. It is advisable to have the plating done by degrees and not all at once, as the metal has a better quality.

Effect of Parallel Condensers on Receiving Antennæ.—In a paper on "The Effect of a Parallel Condenser on the Receiving Antenna," read by L. W. Austin at the March meeting of the Institute of Radio Engineers, it was brought out that the practice of using a variable condenser in parallel with all or part of the inductance in the receiving antenna to receive longer waves is convenient inasmuch as it does away with the necessity of small inductance steps and reduces the total amount of inductance required but is usually found to be less efficient than pure inductive tuning. Tables showing the effects of different values of parallel capacity for two sizes of artificial antenna were shown. The readings were made with a galvanometer replacing the telephone. As the capacity was increased and the inductance decreased, the galvanometer deflection decreased. Replacing one half the inductance by capacity decreased the deflection about one third. Practically the same results were obtained with the real antenna.

The Number of Licensed Wireless Stations.—The annual report of the Bureau of Navigation, Radio Division, for the fiscal year ended June 30th, 1913, showed the following.

Class. Radio Station Licenses Issued.	Number.
Commercial, ship	145
Commercial, land	22
Special, land	17
Amateur	1,312
Total	1,496

Grade. Radio Operator Licenses Issued	Number.
Commercial, 1st	1,617
Commercial, 2nd	315
Experiment and instruction	8
Cargo	1
Amateur, 1st	1,075
Amateur, 2nd	766
Total	3,782

Records	
Total number of inspection records filed	3,916

Since then, up to January 10th, 1914, 465 commercial radio operators' licenses and 679 amateur radio operators' licenses were issued.

Stimulating Plant Growth With X-rays.—Experiments made by Dr. Schwartz, a German scientist, show that X-rays stimulate the growth of plants and of living tissue in general, but in order to produce good results it is required to adjust the value of the rays in order to prevent a destructive action such as can also take place without due care in making use of them. Should the exposure to the rays be too long, the effect can exceed the proper limits and become dangerous. Working upon plants, he finds that an under-exposure of 30 seconds has no appreciable effect of any kind upon the growth, and, on the contrary, a long exposure of 5 minutes is seen to alter the tissues and hinder the growth of the plant. The proper time appeared to be 150 seconds, and shortly after exposure to the rays the plants were so much stimulated that in three weeks' time they had grown to double the height of the other specimens. Such experiments were made with the use of young sprouts, and not upon plants in an advanced state of growth. As to the effect on the tissues of the human body, he finds that in the case of wounds where there is a decrease in vitality of structures, this is stimulated to quite a degree, so that, for instance, an obstinate wound will heal up after a few *séances*. It is well known that the X-rays will produce severe burns upon the skin, but this is caused by a too strong action.

Science

Killing of Two Explorers.—The Bulletin of the American Geographical Society states that there is no longer any reason to doubt the report that the explorers Harry V. Radford, of New York, and T. G. Street, of Ottawa, were killed by Eskimos at Bathurst Inlet on or about June 5th, 1912, as the result of a quarrel.

A New Estimate of the World's Radium Supply.—How large is the quantity of radium salts existing at the present time? At a lecture recently given in France, Besson placed the amount at about seven grammes. The price of a gramme of hydrated bromide of radium is about $80,000 more or less, which means that a gramme of pure metallic radium must be worth about $156,000, or in other words about $78,000,000 a pound.

A Fatigue Museum.—Mr. Frank B Gilbreth, the well-known efficiency engineer, has started a museum of devices for eliminating fatigue in industry The museum is in Providence, R. I. Among the exhibits to be found in the museum are factory stools and chairs of many kinds adapted to many lines of work for both men and women employees Ultimately the museum will contain a permanent exhibit of all kinds of factory devices that affect the physical well-being of the worker. It is not limited to machine safeguards or sanitary arrangements.

The Turco-Persian Boundary has heretofore been one of the problematical features on the map of Asia. As far back as 1843, a mixed commission attempted to define this frontier with only partial success, and since that time repeated efforts have been made by the great powers, as well as the two countries immediately concerned, to complete the task, but the boundary has remained rather a zone of debatable territory than a definite line Finally, in November of last year, a complete understanding on the subject was reached, and a protocol was signed in Constantinople in accordance with which a commission consisting of British, Russian, Turkish and Persian delegates will undertake a survey of the boundary This is expected to require at least 18 months, and will doubtless be productive of interesting geographical results.

The Lowest Temperature Recorded in the Atmosphere.—The "record" low temperature registered in a sounding-balloon ascent is reported from Batavia, where on November 5th, 1913, the remarkable minimum of 91 9 deg. below zero Cent. (—133.4 deg. Fahr.) was found at an altitude unfortunately unknown, as the clock-work stopped during the ascent, but supposed to be about 17 kilometers (10.6 miles). On December 4th, an almost equally low minimum was registered; viz., —90.9 deg. Cent (—131.6 deg Fahr), at an altitude of 16.5 kilometers (10 2 miles). In this case, the apparatus worked satisfactorily and recorded an extraordinary rise of temperature between the above-stated minimum at 16.5 kilometers and a reading of —57.1 deg. Cent. at 26,040 meters (16 2 miles); i. e., a total rise after entering the stratosphere of 33.8 Cent. or 60.8 Fahr. degrees. On August 6th, 1913, a balloon sent up at the same place showed a rise of 18.9 Cent. (34.0 Fahr.) degrees after passing the altitude of minimum temperature. In this case, the balloon rose to 22 kilometers (13.7 miles). These observations show that the name "isothermal layer," applied to the stratosphere, is sometimes a misnomer

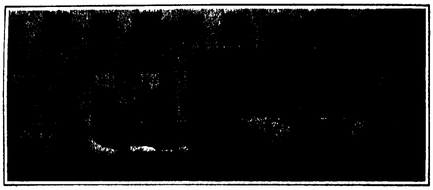
A Comedy in Antarctic Nomenclature.—Apropos of the editorial "Mawson and Wilkes," published in our issue of March 14th, it appears that American geographers have been over-sanguine in assuming that the name "Wilkes Land" was at last indelibly inscribed on Antarctic maps As pointed out in our editorial, a British chart of 1856 shows this name in its proper place. For the past half-century, however, the backings and fillings of British cartographers concerning the name and its application have furnished diversion to Americans endowed with a sense of humor, and have been taken *au grand serieux* by others. The latest episode in the comedy (as we prefer to consider it) takes the form of a map published in our English contemporary *Nature* of March 5th, page 12. Here we find "Wilkes Land" printed where it belongs, but in type which conveys an unmistakable impression of evanescence, while immediately beneath it, spread over the same tract of land, appears in large, bold letters the name "King George V. Land." The latter name is a little over a year old, having occurred for the first time in a wireless message of February, 1913, from Dr. Mawson, who was then in Adelie Land. We believe, however, that Mawson had no intention of giving this name anything like the geographical extension indicated by the chart in *Nature*. A definite statement from him on this subject will be awaited with interest, though it can in no wise affect the validity of the earlier name. For American geographers, at least, the long stretch of the Antarctic between Victoria Land and Kaiser Wilhelm Land will remain "Wilkes Land" until the time—now, perhaps, measurably near at hand—when this portion of the Antarctic is annexed by the Commonwealth of Australia Then, of course, we shall have to accept whatever name the Australian authorities choose to assign to it.

Motor Vehicles on Runners

ALTHOUGH it is possible with little snow on the ground to run a motor cycle with its rubber tires, it has been found impossible to do so when the fall measures several inches. A resident of Galt, Ontario, has solved the problem as shown in one of our photographs. The rubber tires were taken off the front wheel of the machine, and off the wheel on the side car, which is attached to the machine, and runners were bolted to the rims of the wheels. The rubber tire remains on the rear wheel of the machine for driving purposes, but the runner on the front wheel makes the rut, thus permitting the use of the one tire. The motor cycle has been given a thorough test, going through a foot of snow without any trouble at all.

The same idea applied to commercial use is pictured in the second photograph, which shows a three-wheeled tractor hauling a truck through the snow. Obviously, only the drive wheels need contact with the ground. The other wheels make work by crushing through the snow, and if supported on runners materially reduce the work of the motor. The runners may be applied or removed very readily. This is a good suggestion for motor truck owners to jot down for use next winter.

Motor cycle and side car mounted on runners.



Eliminating unnecessary work by the use of sled runners.

Lifeboat Test Off Sandy Hook

NEVER, probably, has greater interest been aroused in the question of lifeboat construction than at the present time. This is natural; for the loss of the "Titanic" is not so far removed, but its lessons are still foremost in the minds of shipbuilders and shipowners; and the past winter, with its unusually boisterous weather and its exceedingly long list of wrecks at sea, in which the lifeboat has been called into constant requisition, has concentrated attention on these small craft as never before. Indeed, next to the subject of hull construction, the matter of lifeboats and their stowage was the most important that came up before the London Conference on Safety at Sea.

We present illustrations of a new type of steel lifeboat which, on two successive days last week, was subjected to severe tests in the presence of Gen. Uhler and the Board of Supervising Inspectors of Washington, D. C.

The lifeboats were designed by Capt. Lundin, and they embody the result of many years of practical experience and observation. It will be seen that they are a wide departure from what might be called the whaleboat type of lifeboat, with which we are all familiar. The craft embodies the stability and great carrying capacity of the raft with the maneuvering qualities of the standard type of boat. This was shown in a series of tests off Sandy Hook on the second day, when a 24-foot boat, heavily laden and propelled by six oars, showed a surprising turn of speed and excellent maneuvering abilities. The boats are built of galvanized sheet iron, and they consist of a decked hull with sides extending about 15 inches from the deck, and provided with weatherboards which automatically lock themselves in the upright position on being raised. When folded down, they form a firm platform to rest the second boat on, no other chocks being necessary for the top boat. An excellent feature is the provision along each side of a very thick continuous fender of balsa wood, which is flat on its inner side, where it lies against the hull, and is molded on its outside to conform with the generally rounded scow lines of the lifeboat. Balsa wood is about 40 per cent lighter than cork, and the fenders alone would assist materially in keeping the boat afloat.

The Lundin boat is of true lifeboat construction with an outer and inner floor, both of steel. The bottom is divided into numerous watertight compartments, each of which is provided with a manhole and watertight manhole cover. The inner floor, or deck, even when the boat is loaded with sixty or more persons, is well above the waterline, and each compartment is provided with drain pipes for self-clearing, equipped with floatable ball valves of a long tried pattern, which prevent the water from squattering up from below. The space provided for passengers is, therefore, self-bailing, and any spray or water that may enter the boat quickly drains away.

In the test on Saturday three boats were put through their exercises; one, a 24-foot metal boat with the Lundin features, of the general ship's boat model, but of very full body and provided with balsa-wood fenders; another, a 28-foot Lundin boat of the scow type, with double bottom; and the third, most interesting of all, was a large 30-foot power-propelled boat, provided with a large watertight steel cabin, driven by a 24 horse-power Standard motor, and equipped with a wireless outfit capable of sending messages for seventy-five miles. The power lifeboat can make six or seven miles, under power, and in the case of shipwreck is capable of taking eight or ten other boats in tow and holding them together, head to sea, and by means of its wireless, bringing up the rescuing ship. The superstructure of the closed cabin is generally semi-circular in cross section, with bulkheads closing in the forward and after ends. In each bulkhead are two large steel doors which are closed against rubber gaskets. The cabin can hold sixty or more people, and ventilation is provided by a series of hinged portholes ranged along the sides. The lower part of these portholes forms a rowlock, and the opening is just large enough to permit free movement of the oars.

The weight of the double bottom and the circular form of the cabin combine to give to these boats absolute self-righting qualities. This was proved in a test which is herewith illustrated, in which the boat was rolled over, by means of a crane, until it was bottom upward, and then released. Within two or three seconds' time it had righted, the heavy weight of the double bottom, combined with the form of the cabin, making this result inevitable. Capt. Lundin believes that a boat of this kind, even if filled with passengers, might be entirely rolled over by a breaking sea, without endangering the lives of the passengers.

The experience already had with steel lifeboats proves that they are able to go through a degree of rough usage without springing a leak that would completely disable any wooden lifeboats.

The difficulty experienced in endeavoring to launch the lifeboats of the "Volturno," shows that the wooden lifeboat is doomed, should it be swung while it is being lowered against the side of a rolling ship, or should it, when in the water, be swept against the hull of the vessel. The wood in such a case splinters badly and heavy leaks are developed. The steel lifeboat, on the other hand, has shown that it can suffer a surprising amount of distortion and come through the ordeal watertight. One of our illustrations shows a standard metallic lifeboat on an American coast liner which

THUS far in our study of the problem of our Navy we have shown:

First, that the necessity for the creation and maintenance of a navy of the first class has been imposed upon the United States by circumstances over which this country had no control. We have seen that, although it was the dream of the Fathers of this republic to found a new nation, which, free from any entangling foreign alliances, should exemplify and perpetuate within its own borders those principles of liberty and equality which had been written into its Constitution, the day ultimately arrived—as it was bound to do—when a resistless destiny thrust this country out into that broad arena of world politics, wherein is being carried on an eternal and inevitable struggle for international pre-eminence. And it was shown, further, that by forbidding the partitioning of China, and by building and fortifying the Panama Canal we have rendered this country the very storm center of that greater struggle for commercial and naval pre-eminence, which the opening of this waterway and the development of the Orient is certain to produce.

Second, we have seen that, although our Government at first responded nobly to the call for a greater navy, and thereby showed its recognition of the fact that the day of our isolation was over, and that we must henceforth accept the burdens and exercise the functions of a great world power—of late years we have been guilty of the inexcusable folly of neglecting our Navy, and this at the very time when we were affirming our world policies with a definiteness and daring for which modern history presents no parallel. It was shown that we have curtailed our naval construction during the years when the nations that would be most likely to challenge our policies were accelerating their own naval construction; with the result that, in the event of dispute, we may have to accept the alternative of an ignoble abandonment of our policies or a crushing defeat upon the high seas.

Third, we have shown that the highly technical and specialized nature of the modern instruments of war has largely obliterated the advantage of certain mental and physical characteristics, in which our people have been pre-eminent; with the result that the issue of future wars will depend more than ever upon the possession of a preponderance of the mere materials of war—that victory in the great day of trial will lie with the fleet which can concentrate the greatest number of heavy guns in a given length of battle line. We proved, furthermore, from the past history of our country that, although the cost of a fleet of fighting ships is enormous, it is positively insignificant in comparison with the cost of unpreparedness, as shown by the fact that policies of retrenchment—that is to say, peace policies that were provocative of war—have saddled this country with an annual pension roll of $180,000,000.

Now since war, with its irreparable loss in life and treasure and its crushing legacy of an enormous annual pension roll, is the greatest physical calamity that can fall upon the country, simple common sense demands that, if any means can be found to prevent war—to insure against its losses—they shall at once be adopted.

Geographically, the United States is so situated that there is only one direction from which a first-class foreign power could wage war with any hope of success, and that is from over sea. Furthermore, no power would dream of sending its fleet over sea unless it could meet us with such a preponderance of force as to render victory certain.

The possession by the United States of a powerful and well-balanced navy, fully equipped and manned, in constant training, and with a reserve of ships and men capable of swift mobilization, would be an absolute insurance against war—IF, AND ONLY SO LONG AS, THAT NAVY WAS MAINTAINED AT A CERTAIN STANDARD OF STRENGTH WITH REGARD TO ITS POSSIBLE OPPONENTS.

"Its possible opponents;" and who are they? England? No; for we could not hope to match her enormous navy; nor is it necessary. Not only do the international interests of that country broadly coincide with our own (the Monroe Doctrine, for instance, was proclaimed with her approval and still receives her moral support), but both the British government and its people are distinctly friendly in their attitude to the United States In witness whereof, take note of her patience in the matter of the Panama tolls, and her admirable self control and tact in the delicate situation brought about in Mexico by the killing of one of her subjects—a kind of international episode in which it has ever been her policy to strike with a swift and unsparing hand.

With the British Navy eliminated as a standard of comparison, we come to that of Germany. Is Germany a possible opponent, and must we match her navy ship for ship? She is, and we must. And we say this in a spirit of the most friendly appreciation of that great country and the genuinely pacific spirit of its present Emperor; and in the belief, moreover, that the Germans, like ourselves, would deplore any such deadlock between our national policies and their own, as would call for the stern arbitrament of war

Now it is a fact, well understood in diplomatic circles, that the whole of Continental Europe, and Germany in particular, regards the Monroe Doctrine with—well, to put it gently, with no friendly eye. The last-named country has vast and rapidly-growing commercial and industrial interests in the Latin-American republics and in South America. It is consistent with the proud, exclusive and self-assertive spirit of the German that he should wish to deal with any complications which might arise in those countries, directly—with the "mailed fist" let us say—rather than by proxy, as in the present Mexican crisis.

And across the Pacific lies that vast Empire of China, fabulously rich in its undeveloped resources, and a tempting prize for the greater European powers, as the events following close upon the Japanese-Chinese war so clearly proved. England, Germany, and France would have created "spheres of influence"—a phrase which, translated into its literal meaning and inevitable consequence, means partition and possession. As against this, we have proclaimed the policy of the "Open door" and "The integrity of China" Add to this the fact that we stand guard (with "mailed fist" if you please) at both portals of the key to the whole naval and commercial situation—the Panama Canal—and it will surely be evident that the United States should hasten to restore her navy to the second rank which it held in 1905, when it showed a positive superiority in strength over that of Germany, our possible opponent.

The question of the strength of a navy is a purely relative one. Our navy is strong or weak, solely in its relation to the strength or weakness of the navies of our possible competitors. The champion wrestler of the village green finds that he is a mere novice in the nearest town, and the subject for jeers and laughter in the arena of a cosmopolitan city

The citizens who, in October, 1911, gazed upon the fleet of 127 ships, including 31 first-class battleships, strung out in the Hudson River from Spuyten Duyvil to Forty-second Street, were not to be blamed if they believed that fleet to be a mighty aggregation of ships and men, ready and able to steam out past Sandy Hook and crush any fleet that could be sent against it. But if they had been told that the German fleet would have reached from Spuyten Duyvil to Staten Island, and the British fleet to Sandy Hook, they would have realized that naval strength, like the skill of the village wrestler, is strictly relative

Many years ago there was created a General Board of the Navy, with Admiral Dewey at its head, for the express purpose of studying this question and drawing up a programme of construction, which, if strictly followed, would maintain the United States Navy at such a standard of strength, that this country could pursue its policies without any fear of challenge or attack If this policy had been followed, the nation, in 1920, would have possessed a battleship strength of forty-eight, with the necessary cruisers, scouts, destroyers, submarines, colliers and supply ships in proper proportion.

"Such a policy," says a distinguished naval authority, "would have fulfilled all the necessary conditions; would have kept the Navy of the United States second to one only; *would in my firm conviction have discouraged the world race in armaments and ultimately tended to their reduction; and most assuredly would have tended to world peace;* for we have no blow to strike ourselves, and however strongly questions of race expansion, trade rivalries, and conflicting interests might urge other nations to strike us, the blow would never be struck, if we possessed a fleet which insured their defeat."

And what became of this programme? It went into the archives of the Government, and there it slumbers to this day And there it is destined to lie until the breath of life is breathed into it by the will of the people as expressed through their representatives in Congress.

The Naval Board programme was never adopted In the give-and-take of politics this, the most vital question affecting the welfare of the nation, was thrown into the political bag in common with such relatively minor matters as rivers and harbors, pensions, good roads and a hundred measures of purely local interest, and it came out of the shuffle cut down to a yearly quota of two battleships per annum. And in four out of the past eight years even that modest programme has been cut in half

Hence, if we are to retain our former standing, we must not only build up to the standard set by the Naval Board, but we must increase the yearly addition by the number of ships omitted. To bring our fighting line up to a standard of strength which will deter Germany from risking a conflict for the control of the Caribbean, we must build six dreadnoughts per year for the next three years and two or three per year for the years immediately following, carrying on this policy until Germany, realizing the hopelessness of any successful challenge of the Monroe Doctrine, shall desist

For it is a fact, too little understood by our Congress, that the ambitious German naval programme, inaugurated a few years ago, was aimed, not at England but at the Monroe Doctrine. Had we maintained the lead which we held in 1905, Germany would never have attempted to outbuild us, England would never have taken alarm at German activity, the added increase in her own and the German programmes would not have been made, and the so-called race in armaments would never have begun

It takes four years to build a battleship and train her crew to full efficiency If we build six battleships a year in 1914, 1915, and 1916, we shall have a first line of battle of 30 dreadnoughts in commission in 1920, and a second line of 16 pre-dreadnoughts In that year Germany will have a first line of 36 dreadnoughts, of which 11 will be battle-cruisers of lighter gun power and less heavily armored than our battleships, she will have a second line of 15 pre-dreadnoughts In a struggle for the command of the Caribbean, we would be operating within easy reach of naval bases—Germany would be nearly 4,000 miles from her own The odds would be decidedly in our favor; and under such conditions Germany would not risk the loss of her fleet in a great naval war She would never send her fleet across the Atlantic, except with a preponderance of naval force so great as to insure a certain and sweeping victory.

Similarly, if our exclusion of the Japanese brought on a war with Japan, involving a contest for the possession of the Philippines, we would be operating at a great distance from our naval bases, and, like Germany, should require a preponderance of naval force to insure success

Battleships are cheaper than battles, and the building of six dreadnoughts per year for the next three years would place us in a position which would effectually discourage the present race in armaments, maintain our policies beyond all fear of challenge, and preserve the peace indefinitely.

But the cost! Six dreadnoughts per year for three years would mean a total of eighteen The $180,000,000 pension bill for the present year alone would cover the cost.

Suggestion for Proviso High School

THE editor of this newspaper is a constantly delighted reader of the SCIENTIFIC AMERICAN, which is authority on American mechanics. We have often thought how beneficial and interesting it could be made if added to the studies in high schools Supposing that all the classes of the Proviso High School could be assembled at a stated hour on each day, and the principal, or a student chosen by him, would read an article from the AMERICAN, and discuss or elaborate on the subject treated, how it would be tapping a great mine of knowledge, for the benefit of the students. In the last issue is an article on the manufacture of automobiles, in the parts of which exact accurateness must be attained. It is intensely interesting and instructive The vital part of an automobile is its piston, and the AMERICAN describes the making of it in the following simple and delightful language:

> "The paper upon which the SCIENTIFIC AMERICAN is printed measures three one thousandths of an inch in thickness, a measure too small to be observed with the naked eye Yet an automobile manufacturer would hold up his hands in horror if you showed him a piston or cylinder that varied from his standard by anywhere near that amount Split this paper into six leaves; wrap one of the leaves around a piston of standard measure and you will have increased its diameter by only one one thousandth of an inch If then you could insert this piston into its cylinder, the cylinder would probably be rejected as too large, or if accepted, you would be informed that it represents the absolute limit of departure from perfect accuracy. We are accustomed to saying that there must not be a variation of a hair's breadth, believing that to be the acme of accuracy, but a hair's breadth may be three one thousandths of an inch or more, whereas in the important part of an automobile motor, one one thousandth of an inch represents the extreme variation permissible, and some parts have to be ground down to within half of a thousandth of an inch"

The article from which we quote is as intensely interesting throughout as is this excerpt. And there are a dozen leading articles equally as fine, treating of life, nature, science, mechanics and kindred subjects which would be prodigiously valuable and beneficial to the students of our high school. And it is so with every issue of the SCIENTIFIC AMERICAN.—*The Advocate* of Melrose Park, Ill.

The Flight Around the World

ALAN R. HAWLEY, president of the Aero Club of America, states that substantial assurances have been received from the Panama Pacific Exposition of the *bona fides* of the offer recently made for a successful flight around the world The $150,000 in prize money offered by the Exposition is actually on deposit in a San Francisco bank. The time for the race has been extended from 90 days to 120 days, and if no aviator wins the race before the expiration of that time, all those still in the air will be allowed to continue flying, and will be credited as winners in the order of their arrival, with certain penalties for each day they fly beyond the established limit. Supply stations three hundred miles apart will house gasoline, castor oil, and mineral oil. Aeroplanes may be shipped over the Atlantic provided any of the contestants feel that they do not care to engage in the hazardous feat of crossing the ocean. The original route from Asia to the western coast of North American has been abandoned, and in place of it by way of the Commander Islands has been decided upon with Sitka, Alaska, as the first landing place on the North American continent after leaving Asia Several cities have offered sums of money for the privilege of being designated as landing places.

The Coin Problem

THE "Problem of the Mint," discussed in our issue of February 7th by Theodore L. De Land, has drawn forth many answers. This problem may elicit a variety of replies. The following arrangement by Salem F. Kennedy is designed to point out the considerable variety of answers to Mr. De Land's query:

Let $x, y, z, \ldots s, w, m$, equal respectively the number of pieces of each minted value. Then

$$x+5y+10z \qquad 500s+1000w+2000m = 50000 \qquad (1)$$

$$\text{and } x+y+z \qquad s+w+m = 200 \qquad (2)$$

Multiply (2) by 250, subtract from (1), transpose and factor, and $249x + 245y + 240z + 225u + 200v = 250(s + 3w + 7m)$ (3)

The total value of the first member of this equation must have a factor of 250, since the second member has such factor. By simple inspection the first member (3) may be reduced to a multiple of 250 by assigning values to x, y, z, etc., as follows:

$x = 10$	2490
$y = 4$	980
$z = 2$	480
$u = 2$	450
$v = 3$	600
21	5000

Substituting 5000 for the first member and dividing (3) by 250, we have $s + 3w + 7m = 20$. $s = 3$, $w = 1$, $m = 2$ satisfies this equation. Whence the following number of pieces, and the total value, affords an *average* of $2.50, which is one of the conditions precedent. They are as follows.

A.	$x = 10$, value	$0 10
	$y = 4$, "	20
	$z = 2$, "	20
	$u = 2$, "	50
	$v = 3$, "	1 50
	$t = 1$, "	2.50
	$s = 3$, "	15 00
	$w = 1$, "	10 00
	$m = 2$, "	40 00
	28	$70 00, average $2.50

The number of pieces required being 200, this result must be increased by 172. By the familiar rule of alligation, comparing u, v, s, w, we have:

$$u : s \ . : 10 : 9$$
$$v : s \ . : 5 \ 4$$
$$u : w \ . : 10 : 3$$
$$v \cdot w :: 15 \cdot 4$$

The number of pieces of u, v, s, w may be increased as follows:

$$(u + s) = n(10 + 9) \qquad (4)$$
$$(v + s) = n(5 + 4)$$
$$(u + w) = n(10 + 3)$$
$$(v + w) = n(15 + 4)$$

for any value of n.

If n equals 1, 2, 3, 4, etc., we must have:

B.
$$u + s = 19, 38, 57, 76, \text{etc.}$$
$$v + s = 9, 18, 27, 36, \text{etc.}$$
$$u + w = 13, 26, 39, 52, \text{etc.}$$
$$v + w = 19, 38, 37, 76, \text{etc.}$$

By the arrangements of A and B, and the "little joker" t (the $2.50 coin), at least 100 different correct answers to Mr. De Land's problem may be written out at once. It is seen that arrangement A lacks 172 pieces that will average $2.50 each. The t value will supply the demand; giving the number of pieces substantially as in form A, with the exception that t will equal 173 instead of 1. Again, $10u + 9s$ produces the average, which added to collection A, leaves $153t$ to be supplied. Formula B may supply a very great number of substitutions, giving decidedly different results in each case, and all strictly correct. An exhaustive search will doubtless reveal correct answers into the hundreds.

Strictly speaking, there is no such thing as an algebraic formula for these problems. They all depend for solution on ingenious arrangement and close inspection.

Sir John Murray

FULL of years and honors, the marine biologist and oceanographer, Sir John Murray, met with sudden death on the 16th of March. Born and partly educated in Canada, he had passed most of his life in Scotland, and was one of the most conspicuous figures in the scientific world of Great Britain. He had celebrated his seventy-third birthday on March 3rd.

In the history of oceanography, especially on the biological side, two names are pre-eminent; Alexander Agassiz and John Murray. Agassiz, the Swiss-born American, collaborated in the task of placing before the world the epochal results of the "Challenger" expedition; and Murray, who took part in that expedition and edited nearly the whole of the fifty-volume "Challenger" report, paid a graceful tribute to the memory of his former colleague when, during a recent visit to America, he intrusted the National Academy of Sciences with a fund for awarding an "Agassiz medal" to persons distinguished in oceanographic research.

The "Challenger" expedition, which in the years 1872-76 carried out no less than 68,000 miles of deep-sea exploration, was the foundation of oceanography as a coherent branch of science. The submarine world was then, for the first time, revealed in a comprehensive way to the insight of man; and this voyage has accordingly been pronounced the most momentous geographic undertaking since the voyages of Columbus and Magellan. Murray, who had previously visited the Arctic regions in a whaler for purposes of biological research, was one of the two naturalists on the "Challenger" under Wyville Thomson, chief of the scientific staff. The failing health of the latter, and his death in 1882, resulted in throwing the whole burden of superintending the publication of the scientific results upon Murray. The execution of this formidable task, as well as his individual contributions to the great report, at once placed him in the front rank of marine investigators.

Thereafter, as the recognised leader in his field, he was obliged to bear the burden of public and private duties which always falls to the lot of the eminent specialist. He found time, however, for numerous researches on his own initiative, including expeditions to explore the Faroe Channel in 1880 and 1882; was a frequent contributor to scientific journals; and received abundant honors, culminating in the K.C.B. in 1898.

The greatest work of Murray's latter years was the execution, with the aid of able collaborators, of a bathymetrical survey of the fresh-water lochs of Scotland, the results of which were published in six volumes in 1910. In the latter year he induced the Norwegian government to send the exploring ship "Michael Sars" on a cruise of the North Atlantic, which proved to be one of the most fruitful enterprises of its kind ever undertaken. Murray defrayed the expenses of this cruise and took part in it. The results of this voyage furnished the bulk of the material for the splendid compendium of oceanography, "The Depths of the Ocean," published by Murray and Hjort in 1912.

It may be worth noting, merely as a curious observation, that Sir John Murray owed a little of his celebrity to the fact that he had numerous prominent namesakes. At the beginning of the present year there were living no less than nine "John Murrays" important enough to be included in "Who's Who," and it can hardly be doubted that each of them shone, to a greater or less extent, with light reflected from the others, since they all contributed in making their common name familiar to the public. The most eminent survivor of the nine is, probably, the London publisher, fourth of his name and line.

The Current Supplement

IN this week's issue of the SCIENTIFIC AMERICAN SUPPLEMENT Dr. H Lieber gives an account of the manufacture and uses of Blaugas.—Dr. L. H. Baekeland writes on the history of celluloid.—Dr. H. Lyster Jameson reports on recent advances made in the investigation of the cause of pearl production in oysters, and shows how such production has been artificially induced.—Our Paris correspondent contributes an article on prehistoric flint mines in Belgium.—Petroleum, its origin and its derivatives, is the subject of an article by D. T Day.—W. P. Davey gives an excellent review of the present status of our knowledge of X-rays.—Prof. H. Geiger's method of counting alpha and beta particles is described by its author.—The subject "Curbing the Mississippi" is treated by J. R Crowe.—The ocean-going, oil-burning, steam yacht "Cyprus," a remarkably fine vessel, is illustrated and described.—C. L. Foote writes on the use of concrete for roads.—The second instalment of G. A. Shook's article on Quantitative Colorimetric Analysis appears in this issue.

The Death of Dr. Edward S. Holden

DR. EDWARD SINGLETON HOLDEN, librarian at the United States Military Academy, died on March 16th, after an illness of some years duration. He was president of the University of California from 1885 till 1888; director of the Lick Observatory, 1888 to 1898. In July, 1902, he became librarian at the United States Military Academy.

Dr. B. E. Fernow, dean of the forest school of the University of Toronto, and Bristow Adams of the United States Forest Service, have just been elected president and secretary, respectively, of the Society of American Foresters, the only organization of professional foresters in the western hemisphere.

The Shuman Solar Power Plant

To the Editor of the SCIENTIFIC AMERICAN:

Mr. Frank Shuman, in his letter on "Feasibility of Utilising Power from the Sun," published in your issue of February 28th, makes the statement: "Our method of generating heat from the sun's rays . . . has already reached an efficiency of 57 per cent." A little further on in his letter he states that the area of sunlight intercepted by the "absorbers" at his Cairo plant is 13,269 square feet, and that they develop 50 horse-power throughout a ten-hour day.

The total amount of energy reaching the earth from the sun is now generally accepted as being nearly two horse-power per square meter of surface perpendicularly exposed to the sun's rays. Allowing for the absorbtion of the atmosphere, at least one and one quarter horse-power is available at the earth's surface. Now as 13,269 square feet is approximately equal to about 1,232 square meters, the energy received by Mr. Shuman's "absorbers" while the sun is shining is equivalent to about 1,540 horse-power. I should like to know how Mr. Shuman figures out that 50 is 57 per cent of 1,540.

The little sun-motors with which John Ericsson experimented in New York during the seventies attained a far higher efficiency than Shuman is getting at Cairo, according to his own figures; yet Ericsson never claimed an efficiency of anything like 57 per cent.

Philadelphia, Pa. E. J. D. COXE.

Sir Henry Blake on the Rubber Congress

To the Editor of the SCIENTIFIC AMERICAN:

At the International Rubber Exhibitions of 1908 and 1911 papers were read by planters, chemists, and manufacturers on everything connected with the production of rubber, and discussions followed that brought to bear the experience of experts from every rubber-growing country in the world. Those papers and discussions were fully reported and reproduced in two books that remain valuable works of reference on every question connected with the industry, in which is engaged so many millions of capital.

As the Fourth Rubber Exhibition and International Rubber Congress opens on the 24th of June, I shall be glad if any persons who desire to read a paper on any subject connected with the growing, curing, or manufacture of rubber, or the possible expansion of its uses, or to take part in the discussions, will kindly communicate and register their names as early as possible with the honorary secretaries of the International Rubber Congress, 75 Chancery Lane, London, W. C.

HENRY A. BLAKE, G. C. M. G., *President.*

Youghal, Ireland.

The Problem of Our Navy

To the Editor of the SCIENTIFIC AMERICAN:

The armaments, whether naval or military, which at some period in civilization would be a great waste, may be the greatest necessity a few years prior to that period Who can say that the progress of the world has not at times been checked by the failure to preserve social development by an adequate protective force? And whether such a social growth is checked or crushed by a crude or a developed people, the loss to the world is beyond computation.

That human and property rights must be respected and protected is elementary. On all sides in every country we see conventions which prescribe the rules for human conduct, and because public opinion is insufficient to enforce these conventions, statutory laws are enacted prescribing penalties for their violation And the people have learned that in a country the enforcement of such a penalty cannot be left to the public in general or to chance, but very definite rules must be made governing the enforcement of the penalty. This has been our experience under the very best conditions where the vast majority of the people have the same standards and ideals. And yet many of the people to whom these facts are simple truths tell us that public opinion is altogether sufficient to regulate intercourse between the nations and foreigners whose standards customs and ideals have developed along divergent paths.

That the force of public opinion is growing cannot be questioned, but at the same time it must be admitted that it has not reached such a unitary development among the people of this world as to make it sufficiently uncomfortable for the individual who has transgressed. It would appear to be unsatisfactory to rely on public opinion to prescribe the rules of law between the countries of the world and their citizens, but we have little else to follow, for the rules of international law and the treaties cover only a few of the questions which may arise. While it consequently may be difficult to determine what the law should be in a given case, a much greater difficulty may be experienced in enforcing the law should an accepted rule be thought to apply. Each of the contending parties would have its national police consisting of army and navy, but the international tribunal which may render judgment in a court of arbitration cannot call on an international sheriff to carry out the judgment.

With the advent of an international sheriff the situation will be changed, for it will be possible to settle the disputes even when people may be unable to see justice in a rule prescribed by a majority of States with whose traditions the people are unfamiliar. But while we are working for the international sheriff, we must protect our physical and industrial development, if necessary by arms, in order that the finer things in our character may have a rich field in which to grow

Tenafly, N. J. EVERARD B. MARSHALL

Flying Around the World

To the Editor of the SCIENTIFIC AMERICAN.

While the writer agrees with your editorial of February 14th on "Flying Around the World" in that the $300,000 in prizes offered for the feat by the Panama-Pacific Exposition directors could be better devoted to aerodynamical research, yet that is also true in regard to many aviation prizes of the past, and it is hardly within the province of the Exposition directors to foster aviation so directly, although we will all agree that some one or several with the means should do so. Yet is it not appropriate that an exposition to represent the entire world's progress should offer a prize for such a trip around the world? However, it should not be compulsory that the same machine or engine be used throughout the trip, although an extra prize or first prize might well be offered for this.

The writer believes that the transatlantic flight for which Lord Northcliffe offers $50,000 is accomplishable with some of the present aeroplanes, with some changes and additions, and that this flight will be accomplished this year; also, that the round-the-world trip can and will be attained next year if certain advanced principles of aviation making for efficiency and safety are carried out; for it requires an average flight of only 200 miles per day to cover the distance of, let us say, 18,000 miles in the 90 days allowed; and some of the minor prizes for partial success are surely worth while also.

In regard to the transatlantic flight, the futility of attempting it with enormous, unwieldy, untried aeroplanes, as some propose, should be apparent. But suppose we take one of the most efficient of the present aeroplanes in regard to useful weight-carrying per horse-power and miles covered per gallon of gasoline. It should have two propellers of large diameter and slow speed of revolution, besides variable angle of incidence and blades inclined slightly forward for further efficiency, the increased amount of undisturbed air acted on in the flaring slip-stream of such a propeller more than compensating for the small loss from the slight angle of the thrust, as demonstrated with the celebrated Garuda propeller of Europe. The propellers should, of course, revolve balancedly in opposite directions by means of a single chain (as can be easily arranged). Then let us add another engine and the other set of such propellers, locating the latter above and below center, with clutches for shifting either engine to either set of propellers. The machine should, of course, be a hydroaeroplane, and for safety there should be lateral resistance surfaces co-operating with the rear vertical rudder for steering, but no fixed horizontal-rudder surface; while an automatic balancing device—instantly suspendable, however, might be added to relieve the aviator when tired

The writer is convinced that a safe aeroplane of more than twice the present greatest efficiency can be made, in fact, aerodynamic experiments already made show that this is possible to-day, and it seems more than probable that such a machine will win the prize for the round-the-world flight next year.

Livermore, Cal. ELMER G STILL

[NOTE.—Since this letter was written, figures in the "World Flight" have been changed, as shown on another page.—EDITOR]

Science in the Class Room

To the Editor of the SCIENTIFIC AMERICAN:

I have noted with much interest your recent editorials on the use of the SCIENTIFIC AMERICAN in the schools. Your letter of recent date asking for further particulars with regard to our use of your journal is also at hand.

A single illustration will serve to make clear our method of using the illustrations You have in the issue for December 27th an article on the building of foundations with hollow steel piles, concrete, and compressed air. I used this article with my class in physics as a further illustration of some work on the uses of compressed air which we had just finished. With the exception of Fig. 2, all the illustrations gave excellent results when projected on the screen with our balopticon Fig. 2 has no sharp contrasts and the pile driving machinery in the background did not come out clearly.

The present tendency in nearly every branch of science teaching is to break away from the nicely formulated, mathematical features of the subject and to give more attention to those applications in daily life which continually meet the student. The botany class no longer memorizes long lists of classifications Instead they are taught life processes and the effects produced by fertilizers and cultivation. Chemistry has ceased to be a series of test tube phenomena and relates itself directly to foods, sanitation, and the industries. More practical plumbing and fewer problems solved by using complicated formulæ, is the slogan of the forward movement in physics

Many schools are demanding a text-book in physics which shall be particularly fitted for girls Teachers are trying to fill the need by introducing such practical problems and illustrations as are found at hand. There is, however, a grave danger in collecting such material. To quote from the preface of a recent text-book "To eliminate or minimize the fundamentals while attempting to teach their applications is not to provide a 'royal road to learning,' but a fool's highway to pretentious ignorance. Pure and applied science are equally essential to a well rounded course The one alone is barren, the other, when not well founded in the first, is superficial, disconnected, and trivial"

The SCIENTIFIC AMERICAN is a type of journal which furnishes thoroughly reliable supplementary material. Not only is it practical, but the treatment is scientifically accurate With a modern opaque projection, the teacher has at hand a powerful aid to class instruction in any subject. A few well chosen pictures projected on the screen make the text-book material concrete and show at a glance the various commercial and industrial applications A good many students will be stimulated by such discussions to read further along such lines.

Nearly all the illustrations appearing in the SCIENTIFIC AMERICAN will give good results with an opaque projector as they stand Where the print is too dark or the contrasts are not sufficiently sharp, the portions to be brought out can be covered with Chinese white and painted over with water colors

The following is a suggestive list of some of the topics which the writer has found helpful in high school:

1. Aviation. No text-book in physics gives an adequate description of this subject A few minutes with the files of the SCIENTIFIC AMERICAN will provide ample material for one or more lectures. Nearly every issue contains one or more illustrated articles

2. Air Pressure and the Atmosphere Air Lock, November 30th, 1912. Pneumatic Tampers, December 7th, 1912. Whistling Buoy, December 14th, 1912. Insufflation Apparatus, December 28th, 1912. Pneumatic Elevator and Grain Lift, July 19th, 1913. Steel Pile Driving, December 27th, 1913 Novel Uses of Compressed Air, July 5th, 1913. Soot and Dust Fall, January 17th, 1914.

3. Automobile and Gas Engine The annual motor numbers, and following issues: Farm Tractors, June 7th, 1913 Diesel Engine, September 20th, 1913

4. Bacteriology Vaccine, June 14th, 1913 Typhoid Fly, July 13th, 1912. Pasteur Institute, December 27th, 1913

5. Cement and Concrete Cement and Its Uses, SUPPLEMENT, March 18th, 1911 Application to Waterways, April 26th, 1913 Trench and Tube Method, March 29th, 1913 Assuan Dam, February 18th, 1913

6. Electricity Steel Furnace, June 7th, 1913 Electric Welding, December 1st, 1913, to November 22nd, 1913 Dussaud's Cold Light, May 31st, 1913 Safety Lamp, January 25th, 1913

7. Heat Solar Power Plant, January 25th, 1913. Liquid Helium, December 27th, 1913

8 Hydro-electric Plants Mississippi River, August 10th, 1912, to September 13th, 1913. California Plants. SUPPLEMENT, August 2nd, 1913

9 Hydrogen. Manufacture for Balloons, December 13th, 1913

10 Oxygen Oxyacetylene Torch, June 14th, 1913, to October 18th, 1913 Living Animals Transported by Oxygen, January 21st, 1911. Pulmotor, February 1st, 1913

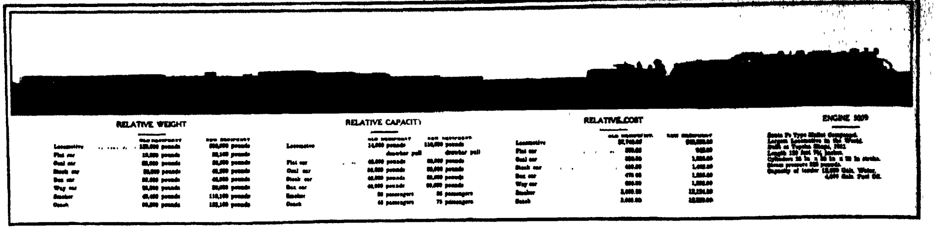
The *Reader's Guide* to the current periodicals will furnish a list of all articles on these or other subjects in which the teacher or students are interested

An occasional article treating some industry from the point of view of the chemistry and physics involved, well illustrated and written in a simple, direct style, would attract our students The natural growth in the circulation of the SCIENTIFIC AMERICAN resulting from such excellent reading habits being formed early in life is obvious.

May I suggest that if you find it practicable to take up such work, your assistants would find it advantageous to experiment a little with opaque projections?

RAY W KELLY.

Pacific Grove High School, Pacific Grove, California.



Santa Fe demonstration train, showing the old (1881) and the new (1911). This shows the increase in the weight of equipment to which the airbrake was successfully adapted.

George Westinghouse

A Great American Inventor

IN the annals of industry it would be difficult to find a personality that fulfills the popular ideal of an inventor so completely as the late George Westinghouse. He began life as a poor boy, he died a wealthy man, thanks to his own efforts His was a strong, hopeful, fighting spirit, and to it he owed as much of his remarkable success as to his wonderful intellectual gifts. The perusal of his life must ever be an encouragement to characters less forceful than his. He began inventing while he was still a school boy; he succeeded brilliantly before he was thirty; he braved what seemed to be invincible opposition, and triumphed; he surmounted all the obstacles which, from time immemorial, all revolutionists—and he was a great revolutionist in modern industry—must surmount if their ideas are to be carried into effect.

Students of eugenics will find in Westinghouse's parentage evidence enough to support their views that great intellectual ability is an inheritable characteristic. He was born on October 6th, 1846, the son of an inventor and of a manufacturer of agricultural implements. He was brought up in an atmosphere that was well calculated to foster in him that marvelous ability which he later displayed Even as a school boy in Schenectady he worked away in his own little shop or in his father's works. At fourteen he had made a model of a rotary engine—a harbinger of the steam turbine with which his name was to be linked in later life.

There is something inspiring in the way that he bounded along to success when he could hardly have put aside his knickerbockers. At seventeen a cavalryman on the Union side in the great rebellion, and a few months later nothing less than an assistant engineer in the United States Navy! It reads almost like a novel.

What his mentality must have been when he was just old enough to vote, one gathers from his abandonment of a classical course in Union College "You are wasting your time here," the president of that institution said to him. "A classical course is nothing for you. You know all that you can learn here of mathematics. You have a genius for invention Cultivate it and you will become a great engineer. The college is holding you back." And so he left college and pursued his way alone. Had he started life in our day he probably would have listened to the lectures of great professors in one of our higher technical institutions, but in those days there were no technical schools in which a man of his caliber could learn anything of real technical worth

It was not long after he left Union College that he invented the airbrake, with which his name is more tenaciously connected than with any other of his numerous inventions. The idea came to him, it is said, as the result of a head-on collision between Schenectady and Troy, which he witnessed.

Obviously meritorious as the invention was, railways would have none of it. Every great invention means a great revolution Revolutions in industry or transportation are no more relished by presidents of manufacturing companies and railways than a Czar relishes nihilist bombs. Westinghouse had to stub his toes more than once in kicking the brick that is concealed beneath the high hat of prejudice, against the "it can't be done" attitude of most so-called business men. He succeeded because he brooked no resistance, because he believed in himself and in his invention. An inventor who is a pessimist is doomed to failure. Mr. Ralph Bagley pledged himself to pay the cost of the first airbrake apparatus that was ever installed on a railway train. But if it had not been Mr. Ralph Bagley it would have been some one else. Tradition has it that the first trial of the Westinghouse airbrake was quite unpremeditated. The train on which it had been mounted rounded a curve; a heavily loaded wagon was wedged in the tracks dead ahead of him; the distance was so small that the ordinary handbrakes could not possibly stop the train in time; only the new airbrake, hitherto untried in actual practice, could possibly avert a disaster. The passengers were thrown out of their seats; for the first time in history a train had been stopped by air, and the first safety appliance in modern railroading proved its worth.

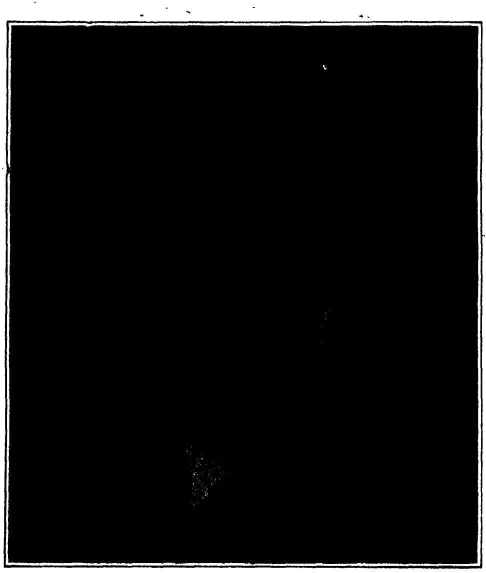


Photo. by Gessford.

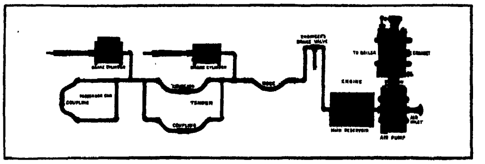
The late George Westinghouse.

Westinghouse was only twenty-two then. That initial success, infinitely more convincing than a hundred successful experiments before critical and skeptical railway officials, started him on the road to success. The Pennsylvania was the first railway to adopt the idea of stopping trains with air. A patent was granted in 1869, and a small shop employing one hundred men began the creation of an industry in which tens of thousands are now employed the world over, and in which tens of millions are invested.

The greatness of an invention must be measured by its economic effect. Gaged by that standard the airbrake is one of the greatest contrivances that ever was conceived by man. It made the modern high-speed train possible; it gave a new impulse to railroad transportation. It is not so difficult to devise engines which will haul cars at the rate of sixty, seventy, eighty miles an hour through space Even on the old Stockton and Darlington road, the first commercial railway ever built, Stephenson's early locomotives sometimes attained a speed of sixty miles an hour. But high speed may not be maintained unless the on-rushing vehicle can be quickly stopped. When his brake appeared the fast train really became possible. In a very real sense, therefore, Westinghouse made it possible to travel in eighteen hours from New York to Chicago.

After the airbrake had been definitely introduced, Westinghouse began to improve it. He was always introducing improvements. Indeed, his personal interest in its perfection did not terminate until about 1901, and even after that he supervised the engineers who adapted the brake to the heavier and faster passenger trains, and the longer freight trains that railways were introducing.

In its development in the hands of Westinghouse himself the airbrake passed through what may be called the "straight-air," "plain-automatic," "quick-action-automatic" and the "high-speed brake" epochs.



The early form of the straight airbrake.

The latest type is known as the electro-pneumatic brake, which will be described and illustrated in an article soon to be published in the SCIENTIFIC AMERICAN. In the evolution of the airbrake, Westinghouse made it a point always to meet existing conditions. Hence, while each one of the types mentioned marked a wonderful advance, not a single airbrake appliance has ever been brought out that would not couple up and work in complete harmony with all prior equipment. Up-to-date airbrake equipment has been furnished for a total of approximately 2,800,000 freight cars, 86,300 passenger cars, and 78,400 locomotives. If this rolling stock were coupled into one solid train, it would encircle the globe on the parallel of Pittsburgh one and one fifth times.

The great changes in braking equipment indicated by these types were necessitated by economic conditions. Very heavy locomotives and heavy passenger cars were necessary to meet the increasing demands of the traveling public, and very long freight trains were required to haul goods long distances cheaply. In the '70s freight cars weighed 10 tons and locomotives 25 tons, with a tractive effort of 7,000 pounds. The average train at that time consisted of not more than 15 or 20 freight cars and four or five passenger cars. In the next epoch freight trains increased to fifty cars—an increase which Westinghouse met by redesigning freight brake equipment. It was thought that the maximum length had been reached; yet to-day freight trains are sometimes 130 cars long. The increased length and the new hazards created were again met by improvements. If these remarkable advances in transportation—made possible in large part by increasing the efficiency and flexibility of the airbrake—do not prove that Westinghouse's greatest invention is more than a mere safety device, we have only to turn to the subway of New York for additional evidence to the contrary.

In 1907 the New York subway handled 258,000 passengers per day; in 1908, 704,000 passengers per day. It was obvious that the transportation facilities had to be improved. It was also obvious that the subway itself was a permanent structure, and could not be enlarged. There was just one possibility of meeting the congestion—to lengthen trains from five to seven cars. To accomplish that feat it was necessary to devise an entirely new type of airbrake. When that was done the Interborough cars ran seven-car trains in 1908, and handled an average of one million passengers daily. But by 1911 the traffic had again become so congested that ten-car trains had to be introduced Again the airbrake equipment had to be improved. This was accomplished by means of the electro-pneumatic brake At the same time the spacing of the block signals was reduced so as to provide for 90 seconds headway. What the improved airbrake has meant to the Interborough Railway system was thus set forth by a prominent official of the road at a recent meeting of the American Society of Mechanical Engineers:

"The Interborough Rapid Transit Company is now carrying as high as 1,200,000 passengers per day in the subway. To go back to the airbrake equipment used only four years ago would mean that 400,000 of these people would have to walk, as it would be an utter impossibility to operate a sufficient number of trains over the road to carry them."

Soon after the airbrake was successfully introduced, Westinghouse turned his attention to railway signals. Only those familiar with the history of railroading know that he was the father of the modern automatic signal. At first he used compressed air to operate the signals, later electricity. Thus the modern electro-pneumatic signal was created.

It is curious that the more important of Westinghouse's railway inventions had for their primary object the saving of human life But the lives to be saved were not merely those of passengers who trustingly paid their fares and took their plush seats, but also of trainmen themselves The automatic car coupler, he felt, minimized the danger of connecting cars, but it did not eliminate the danger entirely Steam and air pipes had also to be connected, and the man whose duty it was to couple them might lose his life if a hasty engineer opened the throttle too soon. So Westinghouse invented, comparatively late in life, a device which would not only couple cars, but also pipes—the whole in a single automatic operation Perhaps the greatest application of these automatic couplers is to be found on the New York subway—great not in the sense that many cars are utilized by the system, but that more than a million passengers a day are carried, whose lives are in a measure dependent on tight joints The order for the subway equipment came to Westinghouse when the idea of automatically coupling the pipes of an electric train was more or less in embryo. Yet so

Discovery That the Sun as a Whole Possesses a Magnetic Field

By Henry Norris Russell, Ph.D.

THERE is probably no one publication which contains in small compass so much new and interesting astronomical material as does the annual report of the director of the great Mount Wilson Observatory. The account of its activities during 1913, which has recently been published, gives in summary form a list of no less than seventy-two results of the year's work, of varying importance, but without exception valuable additions to the sum of astronomical knowledge.

First in the list is a discovery of great importance—made public, with the detailed evidence, some months ago, but not hitherto discussed in these columns—namely, that the Sun as a whole possesses a magnetic field. In other words, the Sun acts like a huge magnet, just as the Earth does. If one could imagine a compass needle to be carried from the Earth's surface to the Sun's, and protected against the destructive effects of temperature, it would point, approximately, at least, toward the Sun's north pole, and the force which caused it so to point would be some fifty times as strong as on the Earth The detection and confirmation of this magnetic force is a triumph of observational precision and skill. The methods of investigation are similar in nature to those which proved the existence of strong magnetic fields in sun-spots, but the quantities which have to be measured are so small that the greatest care was necessary in their determination.

We may recall that, when a luminous vapor is placed in a magnetic field, and viewed in the direction in which the magnetic force runs, the lines in its spectrum, previously single, appear to be split up into very narrow pairs, whose separation increases in proportion to the strength of the magnetic field. But this timing of single lines into doublets is not the whole story. The two component lines of the pair have certain properties which are not found in ordinary light; their light is "circularly polarized." Without stopping to define the exact physical meaning of this term, we may pass to the practically important fact that it is possible to set up an apparatus composed of mica and Iceland spar (and called a quarter-wave plate and Nicol prism), such that, if it is placed in a certain position, the light of one of the two components of the magnetically doubled line passes through it freely, while that of the other will not get through it at all. By turning part of the apparatus at right angles to its former position, we can reverse the situation, blotting out the line which was formerly visible, and bringing into view the one which had before been extinguished.

Such a change in the arrangement of the apparatus, however, makes no difference in its action upon ordinary light. A double line which did not owe its separation to magnetic action would always appear double, and neither of its components could be blotted out at will

It was in this way that Prof. Hale showed that the double lines which appear in sun-spots arose from the action of a powerful magnetic field, which is strong enough to separate many lines into pairs which can be easily separated with a powerful spectroscope, though not all the lines, for the same magnetic field influences some lines much more than others.

The last year was one of minimum sun-spot activity, and hence a very favorable time for the study of the Sun's general magnetism, without interference by the powerful effect of the spot disturbances. Theoretically, it may be shown that if the Sun's general magnetic field were strong enough, the lines in the spectrum would be split up into doubles, such as we have just described, when the light came from points about halfway between its equator and its poles, but not if the light came from either pole or from the equator. Though the doubling would occur with light from either the northern or southern hemisphere, it would be found that the two doublets were not alike Setting up an apparatus such as has been described, and adjusting it so that in the light from some point north of the Sun's equator, the component of the doublet which lay nearest the red end of the spectrum was transmitted, and the violet one extinguished, we should find, on passing light from a point south of the equator into the same apparatus, that the violet component was now transmitted, and the other one blotted out. If the magnetic field under investigation was weak, the pairs of lines would be so little separated that they could not be seen double—they would overlap. But, even so, the edges of the compound line, where one of the components stuck out beyond the overlapping portion of the other, would be circularly polarized, and, by proper manipulation of our apparatus, we might extinguish first one edge and then the other of the compound line, and thus cause a slight shift of its middle toward the unextinguished edge.

This last phenomenon is just what has been found in the Sun. The apparatus was set up in such a way that in a series of parallel strips of spectrum photographed simultaneously on the same plate, the red and violet edges of the line should be alternately extinguished. A line which showed the effect, even to a very small degree, would therefore exhibit something resembling a zig-zag appearance, while unaffected lines would seem straight across all the strips.

Upon making the observations, the majority of the lines showed no effect, but a few not very conspicuous ones gave distinct evidence of a shift—just big enough to measure, but changing from one hemisphere of the Sun to the other, and also with changes in the arrangement of the polarizing apparatus, in exactly the way demanded by theory. The actual amount of the shift is exceedingly small, being, even for the most affected lines, only about 1/4,000th in part of the distance between the familiar pair of yellow lines of sodium; but the numerous and very precise measures of the Mount Wilson observers place its reality beyond doubt. Comparison with laboratory experiments which gave the separation of the two components of the line by powerful magnetic fields, showed that the magnetic forces acting in the Sun were about eighty times as strong as those on the Earth's surface. This is a preliminary value, reduced somewhat by later observations.

Since other lines in the spectrum do not show any such effect, Prof. Hale concludes that the strength of the magnetic force is greatest at the bottom of the solar atmosphere, and diminishes upward. There are various reasons to suppose that the lines which show the effect are produced in the lower part of the atmosphere.

NIGHT SKY: APRIL AND MAY

The Heavens.

The winter constellations are now fast vanishing from our skies. At the hour chosen for our map, Orion and Taurus are practically gone, and Auriga, Gemini, and Canis Minor are low in the west. Leo and Virgo are high on the south and southeast, with the mighty length of Hydra below them bearing the smaller figures of the Cup and the Crow upon its back. Scorpio is rising in the southeast, Ophiuchus in the east, and Lyra in the northeast. Hercules, Corona, and Boötes are higher up in the eastern and northeastern sky. The Great Bear is high in the heavens, just north of the zenith. Lower down are the Little Bear and the Dragon, and still lower Cassiopeia and Cepheus close to the horizon.

The Planets.

Mercury is a morning star all through April, but is best seen during the first week of the month when he is farthest from the Sun. His greatest elongation (or apparent distance from the Sun) is 27 degrees 46 minutes, on the 7th; and on this date he rises at 4:45 A. M., and is easily visible in the morning twilight.

Venus is an evening star, still apparently pretty near the Sun, though really far behind him. She sets at about 7:50 P. M., in the middle of the month, and is easily visible shortly after sunset.

Mars is evening star in Gemini, moving eastward into Cancer at the end of the month. He has greatly diminished in brightness, and appears about equal to Pollux, south of which he passes at about 5 degrees distance in the middle of the month. Jupiter is morning star in Capricornus, rising about 3:30 A. M. on the 1st, and 1:40 on the 31st.

Saturn is evening star in Taurus, setting a little after 10:30 P. M., in the middle of the month.

Uranus is in Capricornus, observable only in the morning hours. Neptune is in Gemini, and is in conjunction with Mars on the 21st, being 2 degrees 34 minutes south of him. The distance between the planets is too great to make this conjunction of any use to the amateur in identifying Neptune, for many faint stars, resembling the planet in a small telescope, will be nearer Mars than Neptune is.

Mars is in quadrature, 90 degrees east of the Sun, on the 10th, and Neptune on the 16th.

The Moon.

First quarter comes at 3 P. M. on the 3rd, full Moon at 8 A. M. on the 10th, last quarter at 3 A. M. on the 17th, and new Moon at 6 A. M. on the 25th. The Moon is nearest us on the 10th, and farthest away on the 23rd. As perigee comes very near full Moon, we may expect unusually high spring tides at that time.

As she makes the circuit of her track, the Moon comes into conjunction with Saturn on April 1st, Mars (pretty closely) on the evening of the 3rd, Neptune on the 4th, Uranus and Jupiter on the 18th, Mercury on the 23rd, Venus on the 27th, and Saturn again on the 28th.

Delavan's comet is now out of sight, as we are on the far side of the Sun; but the latest calculations confirm the earlier ones in showing that it is still a long way off, and approaching the Sun, and that it will probably be visible to the naked eye, and perhaps conspicuous, next autumn.

Princeton University Observatory.

Finding Rare Metals by Spectroscope

MINERAL waters are easily analysed by means of the spectroscope, as shown by M. Jacques Bardet, and this is likely to prove one of the best methods for this work. He sends a beam of light through the water to be analyzed and thence through the spectroscope prism, in order to permit of examining the spectrum, this method revealing very minute traces of metals. He finds the most varied metals in different samples of mineral water, and even the rarest metals, such as germanium and gallium, which are very rarely found in nature.

An Agricultural Car in the Philippines

THE Bureau of Agriculture in the Philippines has adopted the plan, familiar in the United States, of sending a car from place to place over a railway system, specially fitted out for exhibitions, demonstrations and lectures on agricultural subjects. During a month's trip over the Manila Railway stops were made at twenty towns, and in spite of unfavorable weather the car was visited by over 12,000 people, while more than 5,000 attended the nightly illustrated lectures. Improved seeds and a large amount of agricultural literature were distributed.

How the Kinematograph Facilitates the Study of Tissue

Affording Once Undreamed of Opportunities for Detecting Rapid Embryonic Changes

By Genevieve Grandcourt

IN speaking recently before the British Association at Birmingham, Sir Oliver Lodge expressed the opinion that in the interplay of physical, chemical and mechanical forces, "Life introduces an incalculable element. The vagaries of a fire or a cyclone could all be predicted by Laplace's calculator, given the initial positions, velocities, and the law of acceleration of the molecules; but no mathematician could calculate the orbit of a common housefly. A physicist into whose galvanometer a spider had crept would be liable to get phenomena of a kind quite inexplicable until he discovered the supernatural, i. e., literally superphysical cause."

It is the study of the very beginnings of discernible difference between animate and inanimate, of life from its earliest unfolding under the microscope (for example, of the chicken in the egg) that is the province of modern embryology.

Impossible as the development of this science would have been without the relative perfection of the microscope, two other discoveries of recent time have been enlisted in its service; one, the demonstration by Harrison in 1907 that the nerve-fibers of the frog may be artificially cultivated; the other, the moving picture, which affords once undreamed-of opportunities for the detecting of rapid changes in the evolving embryo—changes which may have a very great bearing upon now obscure problems of the origin of life and in pathology.

For a time, experiments in artificial tissue-growth were confined to extracting small particles of living tissue, and causing the proliferation of its cells *in vitro*, that is, in the same way that colonies of microbes are multiplied for bacteriological purposes. The artificial cultivation of the entire embryo was undertaken more recently by Drs. McWhorter, Whipple and Prime of Columbia University.

The method adopted was to put fresh hen's eggs into a specially prepared incubator heated to a temperature of from 99.5 to 104 deg. Fahr., and keep them there from one to two and a half days; then under aseptic conditions to remove the blastoderm, i. e, that portion of the fertilized reproductive cell (ovum) which develops into the embryo and under appropriate conditions, into a living thing.

Early experiments showed that there was difficulty in removing the blastoderm from the egg in such a state as to permit of its artificial growth if it was abstracted either before the so-called "head-fold" had had time to appear, or after the egg had been incubated for a longer period than sixty hours. Success, however, has been had with much older embryos.

If the egg had been in the incubator for a day and a half, and the course of its development was regular, the blastoderm was found to lie on the surface of the yolk, as shown in one of the accompanying photographs. It was then separated from the yolk with scissors, and while lying in a salt solution, was freed from any extraneous matter (such as the granules of the yolk, etc.) which might adhere to it. On being transferred to the glass cover of the chamber in which it was subsequently to grow under the heat of the oven, it was drained of the salt solution, and over it were placed a few drops of fowl's blood; this blood having, meantime, undergone preparation as plasma through being deprived of its cells by centrifuging, and then refrigerated. The blastoderm so prepared was left exposed to the air long enough for the blood-plasma to coagulate, and thus hold the specimen firmly to the glass. One of our illustrations shows the blastoderm after the glass cover has been inverted over the glass cell or chamber, and made "ready for microscopic study and photography" The subsequent process of unfolding is analogous to nature's course in the egg.

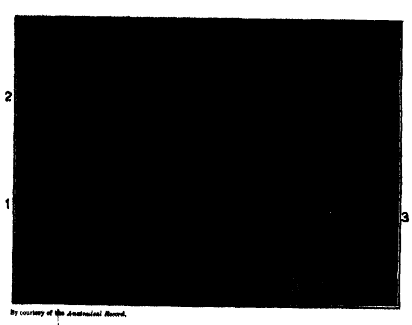
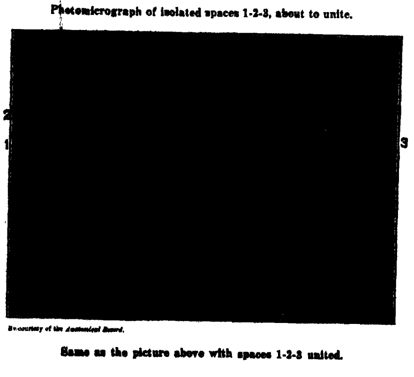
Apparatus for kinematographing tissue growth. A, modified incubator; B, optical bench; C, kinematograph.

One of the many unsolved problems in embryology hangs about the origin and unfolding of the middle of the three layers of the primitive embryo (mesoderm), out of which are evolved the connective tissues, blood vessels and lymphatics. Observations have been made of many forms of life with a view to obtaining light upon the subject, the most trustworthy with regard to the lizard and the chicken. It seems pretty well established that the *mesoderm* unfolds by a uniform process from amphibia to mammals. As soon as it is visible as a distinct layer, two classes of cells are to be discerned in its structure, one of which sets busily to work to form a network of cavities which are the starting-points of the earliest blood vessels.



By courtesy of the Anatomical Record.

Photomicrograph of isolated spaces 1-2-3, about to unite.



By courtesy of the Anatomical Record.

Same as the picture above with spaces 1-2-3 united.

With the expectation that the artificially developed blastoderm would throw light upon the evolutionary process of the entire vascular system, these cavities or spaces were studied under the microscope and photographed. They appeared of unequal size and shape; sometimes, indeed, merely wandering off into undifferentiated tissue, but often having easily traced boundaries Under the magnifying glass, these spaces were seen undergoing constant alteration of size and outline, meeting and flowing into each other—forming channels. At a certain point, the change became too rapid to be followed, and suddenly the observer looked to find the spaces had been swallowed up. Cells or groups of cells were moving in the newly formed channels, the walls of which began to dilate, demonstrating that there was pressure of fluid within When bordering channels met in the form of a net-work, the first heart beat was established.

At this point began an oscillating motion of the cells in the lumen of the channels, and, the circulation being under way, these cells could be seen "breaking off from cell masses," when they "suddenly shot through the channels as if an obstruction were suddenly removed," affording in this way "a remarkable example of the effect of the hydrodynamics of the pumped fluid in these channels."[1]

Observations made from the time of the initial heart beat, and especially on the development of the first two folds of the heart, are essentially technical

In elaborating the study, the obvious

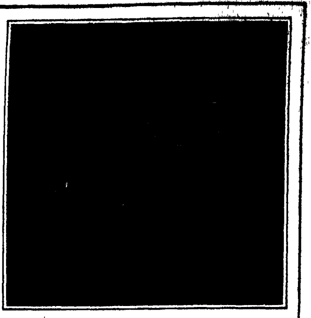
A motor-propelled fire engine racing through the snow.

The Motor-driven Commercial Vehicle

This department is devoted to the interests of present and prospective owners of motor trucks and delivery wagons. The Editor will endeavor to answer any questions relating to mechanical features, operation and management of commercial motor vehicles.



Engine fitted with front drive, virtually a two-wheeled tractor.

Modern Motor Fire Apparatus

By Ross Babcock

A LITTLE more than three years ago motor-propelled fire apparatus was a genuine curiosity. At the end of the year just closed we had 8 important cities without a single piece of horse-drawn apparatus; all motors. Others rapidly are following their lead as is evidenced by the fact that there are now more than 820 cities that have installed gasoline fire fighting apparatus; their total equipment includes more than 2,100 separate pieces. And the investment represents, in round figures, more than $10,500,000! The amount has almost quadrupled in as short a time as 18 months.

Nor are the big cities the only ones that have seen the light and turned their horses out to green pastures. Some of the little ones are just as progressive. Take the cities of Springfield, Mass., and Macon, Ga., for instance. Springfield is about sixtieth in the country in point of size, but it ranks third in the proportion of motor-propelled fire apparatus Springfield's population is approximately 89,000, yet it has no less than 32 pieces of motor-propelled fire apparatus. Macon's inhabitants number about 40,665—Macon has 11 gasoline fire wagons.

According to the latest available figures, there are only 6 States that have more than 100 pieces of motor fire apparatus each. Of these 6, New York leads with 253 pieces of apparatus distributed among 66 cities and towns; the others in the proper order are as follows: Massachusetts, 227 machines in 83 cities; Pennsylvania, 155 machines in 78 cities; California, 149 machines in 53 cities; Ohio, 146 machines in 44 cities; New Jersey, 145 machines in 55 cities.

Economy of operation is one of the principal advantages of the gasoline fire engine; the first cost is practically the last cost, barring accidents, of course, and running expenses which in any case are purely nominal alongside the running expenses of horse-drawn equipment Take the case of the city of Springfield for instance. The Fire Commissioners have prepared a chart which shows (from experience and not in theory) that the average cost of maintenance of 7 pieces of motor-propelled apparatus used as a basis for comparison was $161.89 for a whole year, during which time the average number of alarms responded to by each piece was 140. The cost of horse-drawn vehicles, on the other hand, was $524.18, and the average number of alarms was but 125. The figures speak for themselves.

Chief W H. Jones of the Richmond, Va., Fire Department, said in a recent paper " . . . Its upkeep (referring to a triple combination chemical, pumping engine and hosecart) has been only about 6 per cent of the cost of the horse-drawn, while its efficiency has been 60 per cent greater and it covers double the territory formerly assigned to the horse-drawn apparatus of this particular company."

Here is a conservative estimate of cost made by a reputable manufacturer:

HORSE-DRAWN STEAM FIRE ENGINE.

Feed for four horses	$600
Shoeing horses	72
Veterinary and medicine	80
Blankets, brushes, etc	80
Driver for hose wagon, also stoker and engineer for steamer	2,700
Coal for steamer	75
Harness repairs	40
	$3,647

MOTOR-DRIVEN PUMPING AND HOSE CART.

Tire expense	$120
Gasoline and oil	45
Battery charging	3
	$168

Annual saving of motor apparatus, $3,479.

These figures do not include the cost of building maintenance, which, with motor apparatus, must be less than with horse-drawn, for less room is required for the former.

Let us examine the records that have been made by some of the more modern fire apparatus and in this way bring to light another and very important advantage. For instance, these figures come from the Fire Department of the city of Colorado Springs: Loss in 1911, when it had no motors, $27,000; loss in 1912, with three pieces of motor apparatus, $8,000. Any number of cities report that since the installation of motor fire apparatus, fire losses have dropped off, in several cases by as much as 75 per cent, and in the majority by at least 50 per cent. The city of Pontiac, Mich., estimates that the saving in fire losses in one year paid for its motor equipment. And what is more significant, fire insurance companies look with favor upon such apparatus, and in a noteworthy number of instances material savings in premiums have been effected by property holders.

Motor-propelled fire apparatus itself can be divided into six classes, and in this respect it is pertinent to add that the building of such vehicles requires experience and a square look at the fact that the fire apparatus builder's problems are not those of the ordinary commercial vehicle builder any more than they are those of the pleasure car builder. The successful motor fire wagon must be essentially more or less of a cross between the two. For with the heavy fire engine we have the weight of the commercial vehicle requiring heavy and substantial construction combined with a fair portion of the speed of the pleasure car. Motor trucks seldom exceed 16 or 18 miles an hour, whereas fire vehicles attain speeds anywhere between 35 and 60 miles an hour. Hence their design suggests a number of delicate problems which can only be solved after exhaustive study and experiment.

The six classes of motor fire apparatus include briefly the chief's light runabout, which may or may not carry auxiliary apparatus; the chemical wagon; the ladder truck; the hose wagon; and the pumping engine. The latter may be subdivided to include converted steamers, which are steam pumping engines with gasoline tractive machinery, and gasoline pumping engines which also are driven by gasoline engines. Another division includes combined pumping and chemical engines which also, perforce, carry a quantity of hose.

The chemical engine may range in size from an almost miniature machine with a single small tank to a mammoth six-cylinder machine capable of fighting a really stubborn blaze—and extinguishing it.

Due to the disinclination of municipalities to scrap steam pumping engines which still are useful, quite a number of makers have evolved chassis upon which these pumps can be mounted and so serve out the remainder of their useful lives. In some designs the steam apparatus is mounted bodily upon a special chassis; in another the forward wheels of the en-

RECENTLY PATENTED INVENTIONS

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN.

Of Interest to Farmers.

MANURE SPREADER.—J. A. OLSON, Hildreth, Neb. The invention refers more particularly to the class comprising a pair of spreaders the distance between which is automatically varied by the material passing between the spreaders It provides a spreader in which the pressure produced on the spreaders by the material passing between them is automatically adjusted

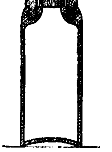
SWEEP STOCK PLOW.—H. T. YOUNG, Florence, S. C. This invention is for use for siding young corn and for the cultivation of cotton throughout its growth, wherein mechanism is provided for permitting the plow to be used toward and from the beam without dismantling the plow or removing the plow from the supporting hanger, and wherein the plow may be held in adjusted position firmly and without any attention from the operator, wherein the stock is supported from the beam, so that it may swing with the plow, and wherein the stock is connected to the plow to swing in unison therewith and to hold the same relative position with respect to the plow regardless of the position of the plow

PRESS—L MATTHEWS, Paris, Tenn. This invention is adapted for use in baling hay and like articles, wherein a pressing chamber is provided, and a plunger movable longitudinally of said chamber and having means of engaging the chamber for guiding the plunger, together with power operated mechanism for reciprocating the plunger.

Of General Interest.

RIBBON DEVICE.—W F. SPRICK, Stickney, S. D. This device is adapted to support and display a roll of ribbon or the like attractively and to so hold the ribbon that any desired amount may be readily unwound and removed without displacing the roll or rumpling or soiling the ribbon, and wherein means is provided for permitting ribbons of different widths to be handled

BOTTLE C V JOHNSON, Goldfield, Nev. This bottle cannot be opened after being sealed by a cover, without first breaking the cover, and the cover cannot be replaced without detection The cap or cover is designed to be fitted over the ordinary neck of a bottle and there is the necessary maximum amount of space within the cover and exterior of the bottle neck, for containing data concerning the filling of the bottle, or of other information concerning the goods therein



BOTTLE.

MEANS FOR CLEANING SEWERS—J. BRUCE, 3258 Thayer St, Pittsburgh, Pa. A small opening is cut in the sewer and the device is introduced through such opening and then rotated by means of a hand brace or other equivalent The device is constructed of steel wire, preferably in the form of a loop, and the free ends of the strands of wire are secured in a suitable clamp which is, in turn, attached to a hand-brace

COMBINED ASH CAN AND LAWN ROLLER.—J. C. B. JARVIS, 1514 76th St., Brooklyn, N Y This invention provides a can having a cover and provided with a sleeve supported by the bottom of the can and the cover for receiving an axle so that when the arms and the tongue are pivotally connected with the axle, the can may also be filled with ashes, and used as a roller for rolling the lawn, tennis courts, etc.

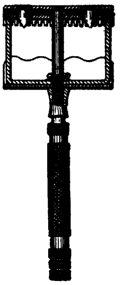
Hardware and Tools.

CAN OPENER.—L. E. HOLMES, Robbinston, Maine. This improvement relates to tools or implements for opening tin cans of fruit, vegetables or the like. Among the objects is to produce a tool of a simple and comparatively cheap construction which is not only easy and reliable of operation, but also which is not likely to damage the contents of the can or receptacle being acted upon.

DRILL BIT—A W. TAYLOR, 812 Rose St., Peckville, Pa. The design of this invention is to provide a drill that will readily cut through hard substances, and a drill that may be turned easily in the drill hole, and that will produce a straight smooth hole to properly receive the cartridge. The invention provides a plural bit, the elements of which may be readily removed and renewed.

SAFETY RAZOR.—L. KALINA, 132 Nassau St., New York, N. Y. The invention provides a safety razor to permit of conveniently assembling the parts for shaving purposes or disassembling the same for cleaning the parts and removal of the blade for stropping or other purposes, the razor being of such shape that when not in use for shaving purposes it can be readily used as a cuff button.

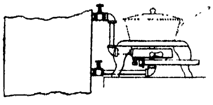
SAFETY RAZOR—S. KITZES, 630 Concord Ave., New York, N. Y. The object of the invention is the provision of a new and improved safety razor of the flexible blade type, arranged to permit of conveniently and quickly assembling and disassembling the parts, and to provide a detachable gathering receptacle for the lather The razor is composed of comparatively few parts, and when in use the lather readily passes into a receptacle which thus forms a shield for the hand holding the razor



SAFETY RAZOR.

Heating and Lighting.

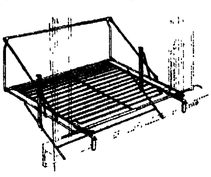
GAS BURNER AND WATER HEATER—J. A. FRISK, 702 W. Illinois St, Urbana, Ill This gas burner is adapted to act as a water heater, the structure shown herewith being characterised by an absence of means whereby the passage of air through the burner structure is prevented The invention provides a burner and heater, preferably of integral construction, the embodiment shown making provision for the utilization of heat below the burner openings as well as along the sides thereof



GAS BURNER AND WATER HEATER.

Household Utilities.

WINDOW CLEANING PLATFORM—H BOTTJER 681 Classon Ave, Brooklyn, N Y The invention relates to temporary platforms or scaffolds, and has particular reference to means for supporting an operator and cleansing materials in the cleaning of windows. He also provides a platform of the character indicated, which may be adjusted to fit any ordinary size of window, and which will be strong and reliable when used in any position of adjustment with respect to the size of the window.



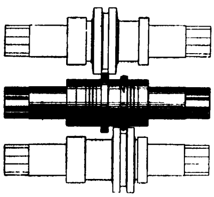
WINDOW CLEANING PLATFORM.

EXTENSION TABLE—V. F NEUMANN, Tivoli on Hudson, N Y This invention embodies a plurality of sections or leaves which, when not in use, can be pushed in or out of the way under the table top. An equal number of leaves are used at opposite ends of the table so that it can be lengthened at one or both ends, as desired. When the length of the table top is increased by the extensions, one or more of said extensions can be employed, so that the top of the table can be lengthened at either or both ends to a greater or less degree

CONVERTIBLE SOFA AND BED.—J. F. KAMPE, 240 67th St., Brooklyn, N. Y. The invention relates to furniture, and its object is to provide a new convertible bed and sofa, which is simple and durable in construction and arranged to permit of conveniently changing the sofa to a bed or *vice versa*. Comparatively few parts are required for accomplishing the desired movement of the back when folding the same to form the back for the sofa or when extending the same to form an outer section of the bed.

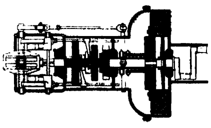
Machines and Mechanical Devices.

SHAPING ROLLS FOR HORSESHOE BARS.—L. T PAGE, Box 104, Wareham, Mass This invention provides means for mechanically creasing and partially punching the bars from which horseshoes are subsequently made, prevents the creeping or misregistering of the rolls with the bars and shoe forming sections thereof, reduces the friction offered by the bars to the rolls when passing therethrough, and provides rolls of the character mentioned, having a simplified and economical construction



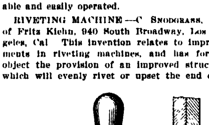
SHAPING ROLLS FOR HORSESHOE BARS

TRANSMISSION MECHANISM—A. B. BROCKMAN and W BROCKMAN, Lawrence, Neb This invention provides a mechanism of the finest possible parts, and of the simplest type, wherein a selective lever is provided for controlling both the clutch and the gear transmission mechanism, and wherein when the selective lever is in neutral position, the gear transmission mechanism is out of mesh, and when moved out of neutral position the selected gear is first fully engaged before the clutch is permitted to close, and wherein the gears are always positively locked with respect to the operating lever, which will be reliable, durable and easily operated.



TRANSMISSION MECHANISM.

RIVETING MACHINE—C SNODGRASS, care of Fritz Kiehn, 940 South Broadway, Los Angeles, Cal This invention relates to improvements in riveting machines, and has for an object the provision of an improved structure which will evenly rivet or upset the end of a bolt, rivet or other similar article with a minimum amount of noise Another object is to provide a rapidly rotating riveting head formed with rotating rollers acting as the contact members for performing the upsetting operation



RIVETING MACHINE.

EXHIBITING APPARATUS—A. P ROESSNER, care of Automatic Electric Sign Co, 814 Macdonough St, Brooklyn, N Y This apparatus is primarily designed for advertising purposes; and it comprises a construction which is automatically actuated and controlled so as to move a plurality of slides or negatives in succession into operative relation with respect to a projecting device by means of which the designs formed on the slides are thrown upon a screen, to be viewed

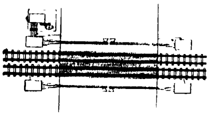
APPARATUS FOR DRYING ARTICLES FORMED FROM PLASTIC MASSES—O EBERHARD, Heidenau, near Dresden, Germany The drying of objects formed from plastic masses, particularly those containing a large proportion of water, is attended with difficulty because if the drying is not uniform strains may readily arise in the material and produce modification of form. By means of the novel drying device used in the present invention defects and difficulties are eliminated owing to the fact that during the drying operation the material under treatment is given a uniform displacement which produces a constant modification in the positions of several parts of the surface of the object relatively to the source of heat and thereby causes this source of heat to act uniformly on all sides

Prime Movers and Their Accessories.

INTERNAL COMBUSTION ROTARY ENGINE—C L RAGOT, 903 Clinton St Hoboken, N J The improvement refers to internal combustion rotary engines admitting of general use, and more particularly to a type of such engine which, because of its lightness, strength, smooth running reliability simplicity and various other qualities, enable it to be used in connection with flying machines

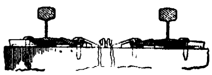
Railways and Their Accessories.

GATE OPERATING MECHANISM J E C JACOBSEN, 29 Fourth Ave, Nyack N Y, and C. A V, J SEGERSTEN, Nyack, N Y This invention comprehends mechanism whereby a train in approaching a predetermined part of a track provided with gates will cause the gate to close automatically, will actuate lamps serving as alarms, and will retain the gates closed and the alarm active so long as the train is present, but when the train departs, the gates are automatically opened and the alarm rendered inactive



GATE OPERATING MECHANISM.

TIE PLATE—W. M GLOTFELTY, Ohiopyle, Pa The present invention has reference to tie plates forming rail chairs and connections between track rails the inventor's object being to provide a tie plate particularly adapted for use with certain connections to prevent the rail from spreading and also constructed so as to receive and retain a tie preservative and prevent the rails from tilting or moving apart.



TIE PLATE.

Pertaining to Recreation.

ARTIFICIAL BAIT—C W STEWART, 120 N 3rd St, Olean, N Y This improved bait is provided with a covering having succeeding layers, each simulating a different fish either as to form or color or both and the layers are adapted to be successively removed to expose different representations in succession until the correct bait is found to successfully attract the fish under the particular conditions, as season and weather or the particular character of the fish being sought

Designs.

DESIGN FOR A SET OF CHARACTER-BLOCKS—DR W C BAKER care of Baker & Bennett Co, 643 Broadway New York, N Y This design is a view in elevation of a set of character blocks representing the complete alphabet and numerals in perspective The mechanical construction of the blocks is so perfect in design that it gives a surprising ornamental effect in each character

DESIGN FOR A SOIL PIPE FITTING D HELLER, Baltimore Md In this ornamental design for a soil pipe fitting the article is shown both in a side view and a longitudinal section view

"The Problem of Our Navy"

A Series of 10 Comprehensive Articles

on the present condition of our Navy, showing its unpreparedness, its present rating among the navies of the world, and what must be done to bring it up to its proper strength and position

Published Consecutively in the Scientific American

Four articles of this series have appeared in the issues: February 28th, March 7th, March 14th and March 21st

These four Copies sent to any address in United States for 45 cents in stamps

No. 1—"How the Navy is Daily Employed"—by *Hon. Franklin D. Roosevelt, Asst. Secy. of the Navy.*
No. 2—"Sea Power and Our Foreign Policy."
No. 3—"The Decline of the United States Navy to Third-Class Rank."
No. 4—"The Price we Pay for Self-Sufficiency and Unpreparedness."

The 5th article appears in this issue

No. 5—"Battleship Strength Necessary to Guarantee Peace."
No. 6—"The Shortage of Scouts, Torpedos and Mines."
No. 7—"The Shortage of Officers and Men."
No. 8—"The Need of a System of Rapid Mobilization."
No. 9—"The Need of a Council of National Defense."

The 10th and concluding article will be written especially for this series by Hon. Josephus Daniels, Secretary of the Navy

MUNN & CO., INC. 361 BROADWAY, NEW YORK

Modern Motor Fire Apparatus

(Concluded from page 270.)

gine are replaced by a three-wheeled tractor, and in still another the forward wheels have been replaced by what virtually amounts to a two-wheeled tractor, the engine standing well out in front and driving through a shaft and side chains.

The vehicle which utilizes but one engine for propulsion and pumping is being widely adopted because of its efficiency and the absence of necessity for carrying two kinds of fuel. All of these machines will run at great speed to a fire, after which a simple clutch serves to disengage the motor from the propelling machinery and engage it with the pump; there is no need to wait for steam and no lack of water pressure because of low steam; incidentally, the unit is generally self-contained in that it carries its own hose; it is independent of the hose wagon which may never reach the scene of the fire because of some accident.

The motorizing of ladder vehicles suggests other problems because of the great length of the equipment. Tractors have been pushed into the breach, so to speak, and have made easy the solution of a problem that might have proved troublesome. At the same time their use permits existing apparatus to be kept in service, for in the majority of cases it is a simple matter to remove the front wheels and substitute the tractor. One of our illustrations shows a water tower with a four-wheeled tractor.

It has been a hard fight to have motor fire apparatus adopted and the antiquated horse-drawn apparatus relegated to the background. But it has been a winning fight from the beginning.

Motor Truck in Snowbound Streets —A Correction

IN an article on "The Motor Truck in Snowbound Streets," published in the SCIENTIFIC AMERICAN of February 28th last, the following statement was made concerning a motor coal truck:

"Altogether during the three days of the storm it ran about 5,000 miles and used up over 60 feet of tire chains. . . ." It is hardly necessary for us to say that the statement is incorrect. It should have read "The truck was a stock machine that had run altogether about 5,000 miles. During the three days of the storm it used up over 60 feet of tire chains," etc.

Lifeboat Test Off Sandy Hook

(Concluded from page 262.)

was damaged in collision with an Atlantic liner in New York harbor. The colliding ship evidently crowded the lifeboat against a hatch, and produced the long straight indentation shown in the photograph This boat was put overboard and towed over a long distance to a yard for repairs, and yet showed no leaks whatever. In spite of this deep indentation the boat would have carried its passengers in an emergency. In tests carried out on the United States Army transport "Kilpatrick," a Lundin steel boat, when half lowered, was pulled away from the ship and allowed to swing back heavily against her hull, with no resulting damage to the boat.

At the conclusion of the tests the three boats were towed from a point several miles outside of Sandy Hook to the Battery at a speed of 13 knots. The first part of the trip was made through rough water, and in spite of this rather brutal treatment, the high rounded bows of the boats carried them comfortably over the seas, and everything was sound and tight when the Battery was reached. The violence of the test is shown in our photograph, taken from the deck of the third ship.

In designing the power lifeboat the broad principle was laid down that all lifeboats, whether with or without power, should always be of such size and construction that they can readily be launched fully loaded, and pushed off the side of the ship as soon as possible after being water-borne. With this in view, the power boat is built with a tunnel by which the propeller and shaft are protected

TRUCKS EFFICIENT?

Many motor trucks can perform twice the work they now do.

Service Recorders will give you the information that makes the increase possible.

In one instance, by using the Servis Recorder, a company reduced the idle time of its truck only 5% and yet increased its average daily haul thereby seven tons.

Another time the Servis Recorder saved its owner the purchase of a new truck.

How the Servis Recorder saves in motor truck and transportation cost will be gladly told upon request to

against any damage while the boat is being launched; and the strength afforded by the double bottom is such that the boat can be lowered when loaded to its maximum capacity of seventy-five people.

How the Kinematograph Facilitates the Study of Tissue

(Concluded from page 269.)

difficulty was the impossibility of following the entire process of the blood-circulation in a single specimen of the artificially developed blastoderm. And it was as a means of getting around this very great obstacle to thorough observation that the kinematograph was employed.

The moving picture catches and reproduces alike the exceedingly slow movements of early tissue growth and cell division, and the subsequent rapid changes connected with the heart and blood vessels, neither of which can be followed satisfactorily in detail through the microscope or by the use of ordinary photography

By the use of the kinematograph, it is possible also to study the primary divisions of the brain, and various other questions---such, for example, as the reason for the invariable position of the heart on the left side of the body; the significance of which knowledge is apparent only to the embryologist.

The device first used in photomicrography, i. e., a camera fastened to a slotted plate braced by an iron framework screwed to the floor (the camera being connected with the microscope) was but slightly modified on the adaptation of the kinematograph to it. "First, a replacement of the lens by a metal tube, second, the substitution of a pulley and interlocking gear-wheels for the ordinary hand-cranking device The gear wheels, two in number, are of different sizes. The larger is screwed fast to the shafting that operates the mechanism within the camera, while the smaller, to which is riveted a small pulley, engages the larger wheel at one side. This reducing gear is so arranged that one revolution of the pulley gives one revolution of the rotary shutter within the camera, the equivalent of one picture."[*]

George Westinghouse

(Concluded from page 267.)

sure was he of himself that he undertook to design the couplers, although there was no time for elaborate tests. The invention was a success from the very first in actual practice.

Fully as important from an economical standpoint as the invention of the airbrake is the introduction of the alternating current, with which Westinghouse's name must also be conspicuously associated as a promoter and engineer. He heard of the experiments made in Europe with alternating currents; his broad mind immediately saw the possibilities of high tensions; forthwith he began experiments in this country That so much progress has been made in this country in high tension transmission is due almost entirely to Westinghouse's initiative. Cities situated within two or three hundred miles of a hydro-electric power plant might not be electrically lighted now had it not been for Westinghouse's farsight.

The introduction of the alternating current was marked by a bitter struggle. Influential as he was, heralded the world over as a great inventor and a great engineer, he found it just as hard to overcome opposition to the alternating current as to induce timid railway officials to adopt the airbrake.

There was more than mere ignorance behind the opposition. Vested interests had to be fought—interests which seem actually to have conspired to prevent the employment of a system which has proved itself of world-wide benefit. For fifteen year the attack continued. Even Edison thought it unwise to encourage the use of the alternating current.

The struggle came to a crisis during the

Make A Family Launch Of Your Row Boat

MAKE this summer one long vacation — a summer filled with boating pleasures. Make it a summer of skimming about over lake and stream to the summer home, camp, hunting or fishing grounds without a lick of work. Forget oars and paddles. Just have the bulliest time you ever had—scooting about with your motor row boat. There's just the price of a Caille Portable Boat Motor standing between you and such sport. If you haven't a row boat, don't let that deprive you of a summer of fun — buy one or rent one — but get one. Next fall, you'll swear the fun was worth ten times the cost of motor and boat. The

Caille Portable Boat Motor

is an absolutely safe, compact little engine that attaches to any row boat by simply turning two thumb screws. It weighs but 55 lbs., generates 2 H. P., and will drive row boats 7 to 9 miles an hour or slow enough to troll. It is steered by a rudder, like a launch—not by the propeller The rudder is of our folding, stone-dodging type (Pat. applied for). The weedless propeller is protected by a substantial fin. Motor can be easily adjusted to any angle or depth of stern. Starts with half a turn of the fly-wheel. Can be run in salt or fresh water. A postal brings you all the details in our beautiful Portable Boat Motor catalog.

Caille Perfection Marine Motors

for larger launches are made in sizes from 2 to 30 H P for both pleasure and work boats. If you intend to build a launch or buy a new motor for your present boat, put your power problems up to us Tell us the length and breadth of your boat and the speed you want to attain We'll tell you the proper type and size of motor to install.

Our Marine Motor Blue Book will be gladly mailed on request Be sure to state whether you are interested in our portable or marine motors when writing. Dealers wanted in unassigned territory.

CHARLES SCRIBNER'S SONS
NEW YORK

World's Fair of 1893 at Chicago. Westinghouse contracted to light the Fair at a price one million dollars less than the nearest bidder. His opponents induced the exposition authorities to exact a bond for the fulfillment of his obligations, believing that no one would become surety for a bond which might be forfeited because it guaranteed the performance of something which had not been attempted in electrical engineering up to that time. Westinghouse promptly furnished three bonds. Next the patent laws were invoked to deter him He was accused of infringing existing patents which covered methods of making incandescent lamps. He merely sat down and invented processes and devices of his own which were obviously not infringements. The Chicago Fair made money; but it made it thanks to Westinghouse The stockholders divided one million dollars among themselves – the exact amount saved by the adoption of the Westinghouse alternating current system

After the success at Chicago, Westinghouse boldly set to work at designing the giant alternators of Niagara. There are ten of them. To this day they are regarded as monuments in contemporary electrical engineering In 1912, by the irony of fate, the Edison gold medal was awarded to him at a banquet of the American Institute of Electrical Engineers for his "meritorious achievement in connection with the development of the alternating current system for light and power." Among those who witnessed that event were engineers who had decried the alternating current as a force that could not be controlled, as a form of energy that should not be used because it might kill.

Two inventions, in the development of which Westinghouse played a prominent part, are the Melville-Macalpine-Westinghouse geared turbine for steamships and the automobile airspring Both inventions have been so fully described in these columns that it is hardly necessary to comment upon them at length again. Interesting, too, is a way of his for controlling the operations of a ship's engines by a device placed on the navigating bridge of the vessel The movement of a lever on the bridge starts or stops the engines, reverses them, and regulates the speed. By its use the engines of the United States steamship "Neptune," a collier, have been reversed from full speed ahead to full speed astern in twelve seconds.

Breadth of vision and receptivity were characteristics of Westinghouse Most inventors can see good only in their own creations Despite all their sufferings and trials they do not often extend a helping hand to fellow inventors Westinghouse was an inventor of a totally different stamp. Not only was he a great inventor himself, but he did more than any other inventor of his time to develop the inventions of others He grasped a new idea with flash-like rapidity Tesla, Nernst, Cooper-Hewitt, Stillwell, Lamme, and a dozen other less important succeeded very largely because of the interest that he took in their labors He spent fortunes in research designed to aid them.

Westinghouse was essentially what the world calls a practical man He could work with his hands as well as with his head. He had learned the use of tools in his boyhood; in his youth he had familiarized himself with every resource of the machine shop, and during the years of his manhood he worked on in the same way as if his livelihood depended on the manual exercise of his mechanical skill. Hence he was a type of employer that men must respect; they felt that he could handle their machines as well as they themselves

It is practically impossible to present a complete view of his economic importance. Perhaps some idea of the vastness of the industries which he created may be gleaned when it is said that there are now thirty-five Westinghouse companies in Europe and America, that they employ 50,000 persons, and that they operate with a total capital of $200,000,000. He himself took out patents on about three hundred inventions, but he controlled as many as 15,000 patents

Packard

SERVICE KEEPS YOUR TRUCKS ON THE JOB

Packard service is based on our knowledge that mechanical delay means unnecessary expense to the truck owner.

The cost of a part may be insignificant, but the cost of an interrupted business schedule is often prohibitive. When a truck is laid up waiting for repair parts, your interest on investment, insurance, driver's wages and garage rent are going on at the same rate, while you pay an excessive charge for emergency hauling.

Delays mean excessive cost that must be added to the first cost of the truck. That is why a truck without service is expensive at any price as compared with a Packard.

Repair parts for Packard vehicles, carried by the Packard factory and Packard dealers, represent an investment of one million, two hundred and fifty thousand dollars.

Packard service means more than keeping repair parts in stock. Every Packard part is ready for quick installation. It is standardized: no filing, no machining, no tinkering. Where a fleet of Packards is in service, the parts are interchangeable in case of need.

The Packard dealer's thorough inspection and written reports insure continuous operation at minimum cost. Our technical men are always ready to give your driver expert assistance.

In short, Packard service makes your transportation schedule a known quantity.

Every time you see a Packard truck, remember Packard service stands ready to keep that truck operating every minute of every working day. Packard service is a part of the truck, a part of your original investment. That is one reason why Packard trucks are predominant in 181 lines of trade.

The Loose-Wiles Biscuit Company, after using Packard trucks for three years, have placed their tenth repeat order which calls for 24 two-ton and three-ton units.

DELCO

ELECTRIC CRANKING LIGHTING IGNITION

One of the foundation stones on which Delco Success has been built, is the Delco Ignition.

Very early in their experimental work Delco Engineers recognized the important part that ignition plays in the operation of any automobile starter.

They realized that without an ignition system that was absolutely right and dependable, no starting device could be successful.

So it was that in the development of an efficient starting and lighting equipment for automobiles the production of a thoroughly efficient ignition was the logical and necessary first step.

That was away back in 1908.

Delco ignition was of a new and distinctive type. It was contrary to established practice. Naturally it met with opposition and criticism.

But it made good.

It made good during those first few years when it was only an ignition system.

It has even more emphatically demonstrated its efficiency during the last three years as an important part of the Delco system of Electric Cranking, Lighting and Ignition.

And finally—the correctness of the principle upon which it is based has come to be so generally recognized that it is being adopted as fully as patent restrictions will permit by many of the most prominent electrical and automobile engineers in the world.

Delco ignition is simply one factor in the success of the Delco system.

It has shown such high efficiency, however, that not a single automobile manufacturer who has once adopted it has been satisfied to go back to the older types of ignition.

It is not as spectacular in its performances as the cranking or even the lighting, but in its quiet, effective way it has played an important part in the revolutionizing of the automobile industry.

You will find the Delco system of cranking, lighting and ignition today on more than 90,000 motor cars and this number is being added to at the rate of over 8,000 a month.

There is a tremendous and steadily increasing demand among thoughtful buyers for Delco equipped cars.

Be sure to write for the Delco book mentioned below

The Dayton Engineering Laboratories Company

Costly Tires

Which Cost You Less Than Most Others

During 1913, the prices on Goodyear No-Rim-Cut tires dropped 28 per cent.

There are numerous tires now which they far undersell. So the question comes: Is any tire worth more than Goodyears?

The Facts are These

In several ways No-Rim-Cut tires are the costliest tires that are built. They are so costly that, when our output was smaller, their price was one-fifth higher than other standard tires.

They are the only tires which are final-cured on air bags shaped like inner tubes. This is done to save the countless blow-outs due to wrinkled fabric. This extra process adds to our tire cost $1,500 daily—an extra cost which no other maker pays.

They are the only tires in which hundreds of large rubber rivets are formed to combat tread separation.

They are the only tires made in a satisfactory way so that they can't be rim-cut.

They are the only tires which carry our double-thick All-Weather-Tread.

The Mileage Limit

No-Rim-Cut tires, on the average, give the limit of possible mileage. We say this after years of research and experiment, which have cost us $100,000 per year.

Our experts in these years have made thousands of attempts to build tires that give more mileage. They have tested the new tires against the old in every way they know. And they say that Goodyear tires as made today mark the mileage limit.

Where We Save

We save by mammoth output, by efficiency and by modest profits. Our profit last year averaged 6½ per cent. It is thus we give you tires like these at present Goodyear prices.

Men have bought, in the past two years, more than two million of them. Bought them because mileage records had proved them the best tires built.

It is easy to build tires worth less than Goodyears but men can't build a tire worth more.

1914

Your car starts in trim for 1914

How will it end?

Friction is relentless.

It steals mileage that belongs to you. It means lost power, and worn metal. In the end it destroys all motors.

A canvass among New York repair shops showed that about one-half of the automobile engine troubles are caused by incorrect lubrication.

Correct automobile lubrication is an intricate, scientific problem.

Motors and feed systems differ widely. *No one lubricating oil can be efficient for all cars.*

This is absolute.

You selected a car that suits you. Now select an oil that suits your car.

Your motor has approximately 1500 parts. To reach all friction points properly your oil must suit *your* motor.

Words and claims cannot meet this condition.

Your business sense must ask:

"Who made the oil?"

"How did they determine its fitness for my motor?"

Throughout the world, the counsel of the Vacuum Oil Company on lubricating problems relating to every class of machinery is sought by engineers who must meet the most rigid efficiency standards

Lubrication with us is both a business and a profession.

The Lubricating Chart, printed in part on the right, represents our professional advice on automobile lubrication. It is a result of the most far-reaching and thorough study of automobile lubrication that has ever been made.

It was prepared after a careful analysis of the motor of each make and model of American and foreign car.

The oils specified have been thoroughly proven by practical demonstration.

For a number of years this Chart, which is annually brought up to date, has been the standard guide to correct automobile lubrication

Make a note of the grade specified for your car Then make sure that you get it.

It is safest to buy in original barrels, half-barrels and sealed five and one-gallon cans. See that the red Gargoyle, our mark of manufacture, is on the container.

On request we will mail a pamphlet on the Lubrication of Automobile Engines. It describes in detail the common engine troubles and gives their causes and remedies

---

The various grades of Gargoyle Mobiloils, purified to remove free carbon, are:

Gargoyle Mobiloil "A,"
Gargoyle Mobiloil "B,"
Gargoyle Mobiloil "E,"
Gargoyle Mobiloil "Arctic."

They can be secured from reliable garages, automobile supply houses, hardware stores, and others who supply lubricants.

For information kindly address any inquiry to our nearest office.

Correct Lubrication

Explanation: In the schedule, the letter opposite the car indicates the grade of Gargoyle Mobiloil that should be used. For example, "A" means "Gargoyle Mobiloil A." "Arc" means "Gargoyle Mobiloil Arctic." For all electric vehicles use Gargoyle Mobiloil "A" The recommendations cover both pleasure and commercial vehicles unless otherwise noted.

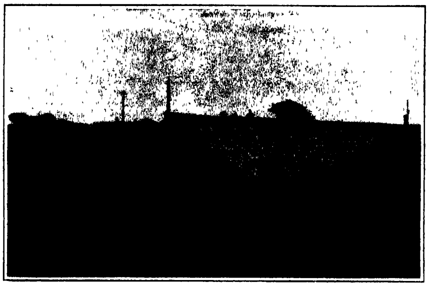
The apparatus by means of which the greenhouses are moved.



Movable greenhouse and the hand-wheel with which it is propelled.

Traveling Greenhouses

By S. Leonard Bastin

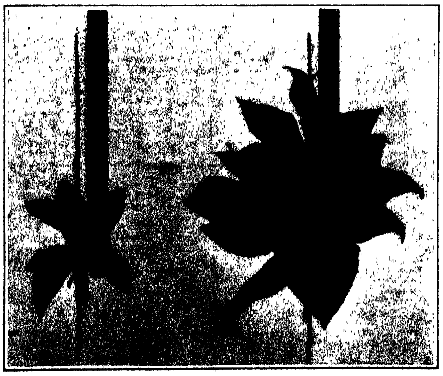
A VERY interesting development in the horticultural world has been the coming of the movable glass-house. In almost all temperate regions, there are occasions when crops of many kinds benefit enormously if a temporary protection of some kind can be given to them. Mr. J. Pullen-Burry of Sompting, near Worthing, England, has at last solved the difficulty by the introduction of his traveling greenhouse, which can be conveyed from different points of the ground to the situation where it will be most useful

During the last few years there have been many efforts to establish the culture of the tobacco plant in Great Britain and Ireland. The variable nature of the climate of the United Kingdom has very much hampered these undertakings. In particular, it may be mentioned that during the last fortnight of its growth the tobacco plants have suffered very much from the effects of low temperature. The foliage has failed to ripen properly, with the result that often enough, a most promising crop has finally turned out to be almost a failure. Some kind of protection is also to be desired in the early summer. Between these two periods the tobacco plant is quite at home in almost any part of England or Ireland. There is no need, and it would of course be very expensive, to have the tobacco crops under glass the whole time. It is just here that the traveling greenhouses are so useful. These are moved over the crops of tobacco at critical times, and for the remaining parts of the season they are used in connection with different crops altogether.

A glance at the accompanying photographs will show the nature of the movable glass-house. A typical house is 100 feet in length, and 14 feet in width. It is fully equipped with a boiler and heating apparatus. Although the structure is estimated to weigh about twenty tons, it can be readily controlled by one man. By simply turning a handle the wheels travel along a concrete way, from which they are prevented from slipping off by a guard rail. The heating apparatus of course goes with the house, and experiments have shown that the whole business of transfer does not take more than about twenty minutes. The question of cost, which is of course a matter of importance, has been carefully worked out, and it is demonstrated that a movable hothouse does not involve more than 20 per cent increase in the expenditure which would be incurred for the ordinary type.

The importance to the horticultural world of this new invention can hardly be overestimated. Many kinds of market-garden crops only require protection during the first stages of their growth. If this can be provided there will be a very much earlier gathering. Yet the actual time which they need spend under glass would only be about two or three weeks Hence it is not always worth while planting them in a greenhouse. Under the movable greenhouse system the crops can be given just as much protection as is necessary, and afterward the glass-house is employed for something else. Thus an enormous saving is effected in all ways.

Movable boiler from which the hot water supply is secured.



Grown in the open. Grown under glass

How the tobacco plant thrives under the movable greenhouse.

Softening Souple Silk

RAW silk is of three kinds, known to the trade as organzine, tram, and souple. The organzine is used for the warp of woven materials, and the tram for the weft Before these are dyed and prepared for weaving, the silkworm gum must be washed out by a process called "stripping" The souple silk is used for the manufacture of the soft fabrics, such as messaline, chiffon, etc., and in order that these materials may retain their softness and pliability and admit of being crushed in the hand without showing any signs of creasing, the souple silk must first undergo a process known as softening.

This process is a very delicate operation, and the quality of the silk depends very much upon the care with which the softening is done In this case the silk is not stripped of the silkworm gum, but is immediately placed in a bath of pure olive oil soap. This bath is made up of about fifty parts of pure water to one of strong liquid soap. The silk is suspended in this bath on wooden rods, and is moved back and forth by two operatives who frequently turn it and keep it in constant motion The bath is heated to 30 deg R., and owing to the continuous agitation of the silk in the bath, the silkworm gum, while not washed out, is made to permeate uniformly throughout the silk

After being treated in this manner for about an hour the silk is removed and placed in another bath of lukewarm water where it is again treated in the same way. This process continues for about fifteen minutes, and is intended only to cleanse the silk The skeins are then removed from this bath and placed in another consisting of about sixty parts of pure water to one of concentrated sulphuric acid heated to 60 deg R Here it is worked back and forth, and frequently turned very slowly for about two hours, or until it yields very readily to a pressure of the finger It is then removed and given two thorough washings in cold water It is then ready for the dyeing.

One of the Largest Forest Nurseries in the United States is conducted by the forest service near Haugen, Montana It is known as the Savenac nursery, and has a capacity of four million young trees a year.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

The Redemption of Mesopotamia

THERE is a romantic as well as an historical interest attaching to the great irrigation works which are being carried on in ancient Mesopotamia with the object of restoring to that historic and richly fabled country something of its one-time fertility. Like much of the land in what was once known as the great American desert, the soil and climate of the valley of the Euphrates are such that if water is supplied, it shows a wonderful productiveness. In earlier times the inhabitants planned and built a system of dams and canals, the remains of which show no little engineering skill; and it is only because of abuse and neglect that the dams have broken down, the canals have silted up, and this once productive land has been transformed into noisome swampland or arid desert

The Turkish government, prompted no doubt by the excellent results which have been achieved in the valley of the Nile, in 1909 authorized Sir William Willcocks to visit Mesopotamia and report upon the feasibility of constructing a new system of irrigation works. In a report published in the following year, Sir William proposed an elaborate scheme of dams, canals, and other accessory works, the total cost of which was estimated at $75,000,000 The Turkish government decided to carry through the scheme in sections, and it authorized the immediate construction of a dam across the Euphrates at such a point as would serve to divert a supply of water to an ancient canal known as the Hilla Channel, which formerly supplied water for the irrigation of a large tract of land extending almost to the ruins of the ancient city of Babylon.

The ancient work consisted of a dam across the Euphrates which raised the level of the river sufficiently to pass the desired amount of water down the old Hilla Branch channel. The work had so far gone to ruin that the Hilla Branch had silted up and the country which it formerly served so well had reverted to the desert condition. It is interesting to note that the site chosen for the new dam is an endorsement of the wisdom of the early engineers; for the new structure is only about 2,500 feet upstream from the old structure. The difficulties of construction were increased by the lack of transportation and the absence of fuel Nevertheless, in less than three years' time, the original channel of the river was closed by a dam, a barrage seven hundred and eight feet in length provided with the necessary regulating gates was constructed, the Euphrates was diverted from its old channel and made to flow through the barrage, and a new diversion was cut from the Euphrates above the barrage to a connection with the old Hilla Branch. The barrage has thirty-six openings each sixteen and one half feet in width. The piers are built of brickwork and the openings are provided with the usual Stoney sluices At one side of the barrage is a lock 26 feet 3 inches wide, and 320 feet long, provided with a pair of gates in the center which divides it into two parts After the barrage was completed, the ground above and below it was excavated, the new channel for the river, 815 feet wide, was formed, and the river was made to pass through the barrage by way of this channel According to *The Engineer*, to which we are indebted for the above facts, there has been built, also, what is known as the Habbania Escape, by which the waters of the Euphrates, when the river is in flood, may be diverted partly into a lake and partly into a large natural depression in the ground. This will serve to prevent, or at least mitigate, the inundations which in times of flood have converted large sections of the adjacent country into morasses.

New York's Sewage Problem

TWO of the most important problems directly affecting the health of a great city—some will be prepared to say that they are absolutely the most important—are those of the provision of an abundant supply of drinking water and of the proper disposal of the sewage. At a cost of nearly $180,000,000, New York city has solved the first problem by a remarkably fine system of works by which an entirely new supply of 500,000,000 gallons of pure mountain water will be brought daily from the Catskill Mountains and distributed throughout the city With respect to this water supply, New York can be said to be fully abreast of the latest practice.

But when we come to the question of sewage disposal, the situation is simply appalling; for day by day this city is discharging into the waters with which it is surrounded, every gallon of the liquid refuse that it daily produces. This has been done under the mistaken belief that since the waters of New York harbor are subject to tidal flow, the sewage is diluted, carried away and lost in the broad Atlantic. As a matter of fact, nothing of the kind occurs On the contrary, the solids, held for a while in suspension, are carried to and fro with the ebb and flow of the tide and are finally deposited in an ever accumulating mass of filth covering the bottom of the harbor; and a very large proportion of it is deposited closely adjacent to the shore line and between the steamship piers

Hence it follows that the investigation which has been carried out by the Metropolitan Sewerage Commission is one of the most important affecting the public health that has taken place in all the history of New York. This commission recently submitted a statement to the mayor, in which it was said that New York city is thirty years behind the times in the matter of sewerage and sewage disposal. Accompanying this statement was one by X H. Goodnough, the engineer of the Massachusetts State Board of Health; and from these documents we learn that whereas the sewage of New York is discharged into the harbor without system or regulation, with results which produce serious injury to the public health and welfare, Boston and the harbor are protected from pollution by main drainage works which serve not only that city, but also a large number of cities and towns in its vicinity.

The Boston situation is capable of furnishing an instructive object lesson to New York city, for up to a certain point the experience of the two cities has been remarkably alike The conditions which led to the construction of the Boston works were like those which exist at the present time in New York. The sewage caused odors and sludge deposits, and, although it was impossible to trace individual cases of disease to the polluted water, physicians declared that no fact was better established than that foul air was unfavorable to health, and that extended changes in the sewerage system could alone accomplish practical good. The sewage disposal works of Boston consist of three ocean outlets to which the sewage, to the extent of about 200 million gallons per day, is taken for screening and settlement and ultimate discharge.

The members of the Metropolitan Sewerage Commission have visited the Boston harbor, and the commission's floating laboratory which was sent there made over one hundred analyses of the water. The water, except in the immediate vicinity of the three outfalls, was of excellent quality. Whereas the average amount of oxygen found in Boston harbor was generally over 90 per cent, it has often fallen below 20 per cent in New York harbor. Comment on this comparison as showing the harmful conditions at New York is unnecessary.

Contracted Computations—Dogma or Scientific Efficiency?

SCIENCE as taught at college is not free from the *dogmatic element, and the man who has the college gates well behind him* is apt still to trail after him a certain amount of more or less age-worn dogma. Indeed, it sometimes requires a certain temerity to attack precepts to which weight and dignity is added by good authority—this perhaps is one reason why so little question has ever been raised with regard to the propriety of the teaching: "Carry every computation only just to so many significant figures as the accuracy of the data warrants Anything beyond this," says the teacher, "is waste of time and energy, and gives a spurious appearance of precision."

This looks very plausible at first sight, but the teacher seems to have overlooked the fact that a certain amount—sometimes a considerable amount—of energy must be spent in determining just how many figures must be retained, at a minimum, in order to obtain the result with that degree of precision which the data permit. We quote from a book review in *Nature*:

> "We venture to question whether teachers do well in this matter. It is customary to work to a significant figure more than will be required in the result; this generally gives the result to the required approximation, but not always. Are we to chance the accuracy, or are we to complicate the process further by an estimate of the trustworthiness of the result? Moreover, the estimation of the number of figures to be retained, even in the normal case, is a matter of no little [illegible]; we have frequently known professors and schoolmasters of good standing to be at fault.
>
> "There appears to be no educational principle at stake, and the question is simply whether contracted methods conduce to speed and accuracy or not. Does the shortness of the contracted calculation compensate for the time spent in deciding how far to contract, and for the chance of error by excessive contraction? For the expert calculator, like the teacher of arithmetic or the observatory computer, it compensates without doubt For ourselves, and we imagine for most people (adults and children), contracted methods in their strict form do not compensate. For us the best way is to calculate stolidly through, and at the end throw away the unnecessary figures, or if the numbers get very heavy, to contract to a modified extent, keeping, perhaps, two or three more figures than a strict contractionist would allow."

Perhaps in this as in most other practical matters, no hard and fast lines can be laid down, and much must be left to the judgment of the individual.

Solar Radiation Measurements at Great Altitudes

THE problem of eliminating the effect of absorption by the earth's atmosphere in determinations of the solar constant of radiation has never been solved in an entirely satisfactory manner. The ideal solution would be to expose the measuring apparatus above the utmost limit of the atmosphere, and, although this is impossible, an approximation thereto consists in *sending up a pyrheliometer attached to a balloon* to the greatest height attainable. The first attempts to carry out such a plan were made last summer by the Smithsonian Institution, in co-operation with the United States Weather Bureau. A modified form of the silver-disk pyrheliometer was used. As it could not be kept pointed at the sun, the disk was placed horizontally, and the thermometer was contrived to record its temperature by photography on a moving drum. The disk was alternately exposed to the sun and shaded by the action of a shutter, moved by clockwork. Although in five ascents, on successive days, altitudes up to 20½ miles were attained, the freezing of the mercury in the thermometer unfortunately prevented records from being made above about eight miles. Mr. C. G. Abbot, under whose direction these observations were made, states that "all the measurements unite in indicating values of the solar radiation at altitudes of 10,000 meters (6.2 miles) and higher which fall below the value of the solar constant of radiation as obtained by other methods;" a very interesting result, despite the fact that this method is somewhat rough as compared with pyrheliometric measurements at the earth's surface. This year it is proposed to repeat the experiment with improved apparatus, which will include, *inter alia*, an electrical heating device to prevent the mercury in the thermometer from freezing. Mr. Abbot hopes to reach altitudes up to 40,000 meters (nearly 25 miles), at which the atmosphere is so exceedingly tenuous that the observations, if successful, should indicate very nearly the true value of the solar constant.

Defining the Cyclecar

THE fog that has obscured the exact meaning of the word *cyclecar*, as applied to that type of vehicle which is neither motorcycle nor full-sized automobile, is in a fair way to being dissipated. Ever since the cyclecar first appeared, the question of its proper classification with regard to other vehicles has been a moot one. Now, however, the Cyclecar Manufacturers' Association, but recently formed and representative of the majority of American manufacturers, has set its stamp of approval upon a specific definition; places vehicles other than full sized automobiles and motorcycles in three distinct classes, the first class including cyclecars, the second class slightly larger vehicles which are arbitrarily styled light cars, and the third class still larger vehicles which are to be known as small cars. According to the definition, a cyclecar is a vehicle having one engine of not more than 70 cubic inches piston displacement, the vehicle to weigh less than 750 pounds. A light car is described as a vehicle having one engine of from 70 to 100 cubic inches piston displacement and weighing between 750 and 950 pounds; and a small car is a vehicle having an engine with between 100 and 175 cubic inches piston displacement and weighing between 950 and 1,150 pounds. There are no other restrictions or limitations. Doubtless, the definition of these vehicles, which all heretofore have gone under the generic term cyclecar, will serve at least to slow the flood of inquiries with which the automobile industry and all connected with it have been inundated.

Science

Automatic Pianos have been installed on the restaurant cars of one of the principal railways in Argentina.

Exploration of the Brahmaputra.—According to the *Scottish Geographical Magazine*, Captains Bailey and Morshead have returned to India after an arduous journey in the dangerous country of the Abors, and announce that they have conclusively proved the Tsangpo and the Brahmaputra to be one river, thus settling one of the most interesting of geographical questions. At the same time they bring the surprising news that the supposed falls of the Tsangpo do not exist.

The Sootfall of Pittsburgh, as determined from careful measurements during the past year, ranges from 595 to 1,950 tons per square mile per annum. The destructive possibilities of this immense deposit may be illustrated by stating that if an equal amount of lampblack were ground with oil so as to form black paint it would cover from 17 to 57 square miles with two coats. Statistics of sootfall at certain places in Great Britain are as follows: Industrial section of Leeds, 529 tons; center of London, 426 tons; Glasgow, 820 tons.

Upper-Air Observations in India.—At the instance of the Royal Society, the meteorological service of India is about to embark on a campaign of investigations of the upper air which is expected to extend over a period of ten years. The headquarters of this work will be at Agra, where sounding-balloons carrying registering apparatus will be sent up about twice a week to the greatest heights attainable. There will probably also be four or five sub-stations, from which similar balloons will be sent up to moderate heights; say about 12,000 feet.

Scientific Balloon Ascents by human beings have, to a large extent, been rendered superfluous by the invention of automatic devices for registering the temperature, pressure, etc., at great altitudes; nevertheless, there are still many kinds of scientific observations in the upper air for which a personal observer is essential. A notable series of 16 manned-balloon ascents for the investigation of a wide range of problems has recently been executed at Halle, Germany, some of them to great altitudes (30,922 feet in one case). In one of these ascents, radio-telegraphic apparatus was carried in the balloon, and studies were made of the audibility of wireless signals at different altitudes. In others, specimens of air were collected for analysis up to 29,850 feet; the physiological effects of great altitudes were investigated; and measurements of electrical potential gradient and conductivity of the air were made up to 27,887 feet—an altitude greater than that at which any measurements of atmospheric electricity have ever before been made.

The Kara Sea Route to Siberia was the subject of an address delivered by Dr. Fridtjof Nansen before the Imperial Russian Geographical Society on his return to Europe, after making a journey to the Yenisei on the steamship "Correct." The speaker urged the Russian government to establish a wireless station at Dickson Harbor, at the mouth of the Yenisei, in addition to the three that have been established at the entrances to the Kara Sea. He also recommended that a small fleet of sailing vessels with auxiliary motors maintain an ice patrol in the Kara Sea during the season of navigation, reporting their observations by wireless to the land radio stations, and that this service be further supplemented by means of aeroplanes. It is understood that these recommendations will be carried out by the government, and that a subsidy will be paid to the firm making the most satisfactory arrangements for regular steamship service between a port on the Baltic Sea and the mouths of the Ob and the Yenisei. The vessels must fly the Russian flag, and give preferential rates to Russian goods.

A "Greenwich Time" Monument in France.—On March 11th, 1911, standard time of the meridian of Greenwich was adopted for official and railway purposes in France, in place of standard time of the meridian of Paris. Funds are now being raised to erect a "monument de l'heure" at the point where the Greenwich meridian intersects the northern coast of France; viz, at the seaside resort of Villers-sur-Mer (department of Calvados). A model of the proposed monument, designed by the sculptor Leduc, was exhibited at the Salon of 1913: Phœbus in his car, drawn by fiery steeds, holds aloft a lance with which he points out the standard meridian, while the Gallic cock, surmounting a terrestrial globe, is in the act of crowing to announce the hour of noon. The latter feature is an allusion to the fact that the International Time Conference of last October selected the wireless station on the Eiffel Tower as the central official time-piece of the world. Writing in the *Comptes Rendus*, M. L. Lecornu calls attention to the coincidence that the location chosen for the monument is very near the port of Dives, from which William the Conqueror sailed for England, thus recalling the historical connection between Normandy and Great Britain, and is also not far from the birthplace of the great astronomer Laplace. Lastly, the date on which the new time was adopted in France was the centenary of Leverrier.

Astronomy

Partial Eclipse of the Sun.—Those who live north of a line drawn from Washington to Indianapolis will be able to see a partial eclipse of the sun, if clouds do not intervene, at sunrise on April 21st. The path of totality of this eclipse will be north of 70 degrees latitude and will cross Sweden and southwestern Russia. The United States Naval Observatory has issued full calculations and maps of the eclipse. Since the observatories at Riga and Kief are in the path, it is not likely that any extensive expeditions will be sent out.

Globular Masses.—By studying the distribution of stars in the globular masses 10 Centaur, 47 Toucar and 13 Messier, E. Pickering has deduced, from observation, the apparent density, i. e., the number of stars per unit of surface at different distances from the center of the mass; he concludes that the distribution is the same for bright stars as for feeble ones, and also that the law of distribution is the same from one mass to another. H. von Zeipel has endeavored to deduce, from the apparent density on the celestial sphere, the true density in space, with partially satisfactory results. The distribution of stars near the center was represented in a satisfactory manner, but the density at the boundaries is less than that required by the theory. In a new memoir he arrives at a novel conclusion. Each of these masses is a gigantic system containing about a million stars; the number of stars visible on a plate is not the hundredth part of the total number.

Absorption of Gravitation.—Dr. Bottlinger, of Munich, has made a very interesting attempt to show that gravitation is absorbed in traversing a medium, so that the interposition of a third body between two others affects their mutual attraction. He is of the opinion that the attraction of the Sun on the Moon is enfeebled when the Earth comes between them, i. e., when there is an eclipse and it is to be remarked that the effects of two consecutive eclipses nearly destroy one another. Dr. Bottlinger admits that the enfeeblement of gravitation depends on the density of the medium traversed and is, therefore, obliged to construct an hypothesis respecting the interior constitution of the Earth. The perturbations of longitude, calculated in this way, from 1834 to 1909, are translated into a feeble oscillation of which the period is nineteen years. The epochs of maximum and minimum correspond exactly to those which have been found empirically by Newcomb. It remains to be seen whether the application to a longer interval of time will not show that on this theory we reach results which are irreconcilable with the facts.

Luminosity of the Sky Near the Sun.—Measurements have been made on the luminosity of the sky in the immediate neighborhood of the Sun. The intensity of this luminosity decreases very rapidly as we leave the edge of the Sun, and to determine the law governing this decrease it is necessary to mark out spaces in the neighborhood of the Sun, to measure their distance from the Sun, and to determine the surface luminosity in comparison to that of the Solar disk. For a certain distance the decrease in luminosity from the edge of the Sun, with a uniformly pure atmosphere, is perfectly continuous and symmetrical on both sides. With equal brightness of the sky, the surface luminosity in the neighborhood of the Sun depends on the height of the Sun; it diminishes as the height of the Sun increases. For equal heights of the Sun, it diminishes as the blue of the sky is more intense and, in consequence, as the local luminosity, measured by eliminating the rays of the Sun, is feebler. From the existence of certain perturbations in the curve of luminosity, it is proved that halos exist in the immediate vicinity of the Sun. Measures of the relative luminosities of the sky in the neighborhood of the Sun is a very delicate test of the purity of the atmosphere.

Origin of Structures on the Moon's Surface.—In an interesting letter to *Nature*, Mr. Fisher mentions a few explanations which have been given to account for the present appearance of the Moon's surface. It seems very doubtful whether the so-called craters, which are such a marked feature on the Moon, are really of volcanic origin. Dr. Johnston-Lavis writes, "the more I compare the Moon's surface with volcanic vents in different parts of the World, the less I see a resemblance between the two," and "the more does the planetoid and meteorite projectile theory become acceptable." A very interesting theory was outlined some time ago by G. K. Gilbert. He remarks that, if the so-called craters of the Moon were due to the impact of meteors, their form would be, for the most part, elliptical, whereas, in fact, they are circular. His own theory is that the Earth was at one time attended by a ring similar to that which encircles the planet Saturn, and that this afterward "gradually coalesced, gathering first around a large number of nuclei, and finally all uniting in a single sphere," the Moon. Mr. Fisher suggests that in the disruption of the Moon from the Earth, the material was scattered and that the circular so-called craters have been caused by the impact of fragments of the solid crust and that the mountains of the Moon are angular portions of the Earth's crust.

Automobile

Number of Electric Cars in Use.—According to statistics which have but recently become available, there are approximately 37,000 electric vehicles in use in the United States. Of this number, about 25,000 are passenger cars, the remainder being commercial vehicles. The city of Chicago, of course, holds the record with 2,850 vehicles. New York is next with 2,000 and Cleveland third with 1,800.

Motor Population of New England.—According to the latest authentic reports there are at present 119,115 motor-driven vehicles, including passenger and freight, in the New England States—Maine, New Hampshire, Massachusetts, Vermont, Rhode Island, and Connecticut. Inasmuch as the combined population of these States is 6,552,681, this means that there is one motor vehicle to every 55 inhabitants During the past year, the number of vehicles registered in these States has increased by nearly twenty-five per cent. The New England registrations represent about one tenth of the number of cars in the United States.

Peening Instead of Grinding Valves.—By way of eliminating waste of time and the great amount of labor involved in grinding poppet valves to a proper seat, an American company recently has adopted the somewhat novel expedient of peening them to their seats. For the purpose a special type of hard valve is used It is first accurately reamed, as is the seat, after which it is struck a number of rapid, fairly light blows with a compressed air hammer. The resultant seat is said to afford a better fit than that obtained by grinding and to resist leaks and corrosion longer and the whole operation can be completed in from 20 to 30 seconds—a material saving of time over even the best of previous methods.

Substituting Suction for Magnetism.—A small magnet on a long handle is an excellent thing to have about a motor repair shop for lifting small nuts, bolts, etc , out of obscure places. It is open to the objection, however, that it will serve only for iron or steel articles. To overcome this objection there has just been placed upon the market a somewhat similar device in which suction takes the place of magnetism. The lifter consists of a rubber suction cup at the end of a handle which is hollow and which is connected to the hose leading to an exhaust pump. A small thumb valve affords control and there is a hook for dislodging small articles. The device is intended primarily to lift sheet metal stampings from under die presses but is useful in many other ways

Cyclecar Popularity Increasing.—The popularity of that little type of automobile which has come to be styled "cyclecar" appears to be increasing, though so far the vehicle has not cut a very wide swath for itself. There are now said to be upward of 30 companies building cyclecars, most of them located in Detroit, though not many cars have appeared on the streets. One feature of the movement which may perhaps have been overlooked in some quarters is that makers appear to be finding a ready sale for their products on the other side of the Atlantic. Several instances are on record of American makers having signed contracts for substantial numbers of cars One maker, in fact, has just announced the consummation of a British contract for 10,000 cars. In the main, however, American makers are confining their efforts to supplying the American market.

Another New Automobile Motor.—Another new type of automobile motor has been added to the long list of those that may be styled out of the ordinary And as might have been expected, the newness concerns itself chiefly with the valve system. Instead of having the accepted type of poppet valves, this one has a new kind of sliding valves Across the top of each cylinder there are transverse cylindrical ports approximately the same diameter as the bore of the cylinder. In each port there is a plug with a space between the plug and the cylinder. In this space there is placed a segmental valve which is reciprocated so as to open and close alternately two ports leading to the intake and exhaust manifold The segmental valves are operated by push rods and cams In order to prevent the valves sticking, they are lubricated by pressure. The engine is now undergoing a series of efficiency tests.

For Foot Control of Steering.—Because a motor car operator's hands and arms occasionally become tired through holding the steering wheel for long stretches without rest, a Canton, Ohio, company has perfected an attachment whereby the steering of a vehicle can be controlled with one of the operator's feet, temporarily. The device consists of a formed pedal which is attached to the lower end of the steering column When the operator's foot is placed upon the pedal it drops a fraction of an inch, thus establishing it in connection with the steering gear Tilting the foot forward and backward then changes the direction of the steering wheels When the operator's foot is removed from the pedal it springs up and is thus disconnected, when the steering then is accomplished through the regulation steering wheel. It is pointed out that the apparatus possesses the advantage that it permits the operator to drive with his hands in his pockets during cold weather.

A New Theory of Sunspots

By Dr. E. A. Fath

AT the meeting of the Royal Astronomical Society in London on December 12th last, Prof. H. H. Turner, Savilian Professor of Astronomy in the University of Oxford, presented a new and unique theory of sunspots. The full text of the paper has not yet been received, but Prof Turner has given the outlines of his theory in the London *Times* of December 13th. At first glance the theory appears to be quite fantastic, nevertheless its author has been of great service in the modern development of astronomy, and whatever he says deserves a respectful hearing.

The outline of the theory is as follows:

It is well known that at times there are many spots visible on the sun, while at others they are few or entirely wanting. Observations extending over many years have shown that the number of spots varies with some regularity, the average period from maximum to maximum being about eleven years. A few years ago Prof. Schuster found evidence of other periods of about five, eight, and thirteen years. While investigating the problem recently Prof. Turner found certain breaks in the sunspot series at about the dates 1766, 1800, 1833, 1866, and 1900. In these years meteor showers known as the Leonids were particularly active. It, therefore, appeared that there might be a connection between these meteors and sunspots.

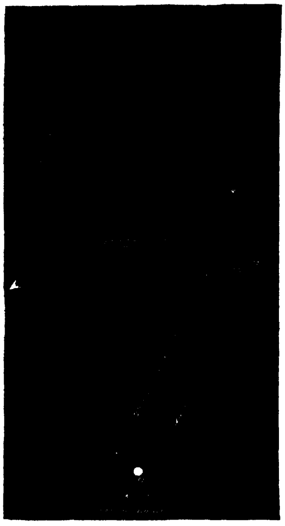
The Leonids themselves are known not to approach very near the sun, and it was therefore impossible to see a direct connection. Some intermediary was therefore required. This intermediary was supposed to be what might be called a subsidiary swarm of meteors which graze the sun at their nearest approach, and also pass so near the orbit of the Leonids that their motion is disturbed by the attraction of the latter when the main swarm of Leonids happens to pass this point.

This subsidiary swarm might have come into existence at a time when the main Leonid swarm was near Saturn The planet itself probably drew in the larger portion to itself just as the earth draws in shooting stars, but those portions of the swarm which passed through the rings might collide with the components of the latter, and so affect the motion that both meteors and the particles of the rings might be freed from the control of the planet and fall toward the sun Some would fall directly into the sun and the others would either graze or pass very near the surface of this body.

The dates of the possible encounter of Saturn and the Leonids are given, and, with one exception, these are preceded by a scarcity of sunspots and followed by a marked increase. The last encounter was in 1863 In March of that year a Greenwich observer noted that the inner dusky ring had so increased in brightness that it was nearly as bright as the other rings. This observer therefore may have actually seen the result of the bombardment of Saturn's system by the Leonids. Seven years after this came the great sunspot maximum of 1870. At about this time disturbances in the motion of Saturn in its orbit were noted. If this disturbance was due to the Leonids then the mass of this meteor swarm must be far greater than is usually supposed.

If we can assume that some of these meteors have a large mass, then their fall into the sun must produce a considerable disturbance, for they strike with a velocity of about 400 miles per second. This disturbance manifests itself as a sunspot.

We have thus briefly stated the main points of this latest sunspot theory. It leaves many things unexplained, such as the peculiar distribution of the spots in latitude, why the earth does not encounter huge meteors at times, etc It may be that the apparent connection of breaks in the sunspot series with the Leonids may be nothing more than a curious coincidence, and it certainly looks as if the author had gone far afield to find a cause which may reside in the sun itself. Nevertheless, before passing judgment on this unique theory, parts of which Prof. Turner himself says have "an appearance of wild speculation," it will be well to await the publication of the complete paper as presented to the Royal Astronomical Society.



Prof. H. H Turner suggests that there may be a connection between the meteor showers known as the Leonids and sunspots Some intermediary, however, was required, because the Leonids do not approach the sun—an intermediary found in a subsidiary swarm.

Prof. H. H. Turner's theory of sunspots.

First Magnitude Stars

By Frederic Campbell, Sc.D., Late President Department of Astronomy, Brooklyn Institute

THE world over and the year through, 8,000 stars are visible to the naked eye. Except the five visible planets of our own solar system, all these are suns. Seen through the best telescopes, their number leaps to 100 million; and photography raises it to one million million. So says the distinguished scientist, Sir E. Ray Lankester.

To become familiar with such a host is absolutely hopeless. But, just as we may have a dozen or two familiar acquaintances among the billion and a half people on earth, so is it possible to know a few of the most splendid stars. The most learned astronomer, in fact, carries at his belt but a short string of stellar scalps. The first magnitude stars are but twenty in number; and of these only fifteen are ever visible in our northern latitudes. With these fifteen, or even twenty, splendid luminaries there is *no excuse for any* man's not having acquaintance, as with so many genial friends.

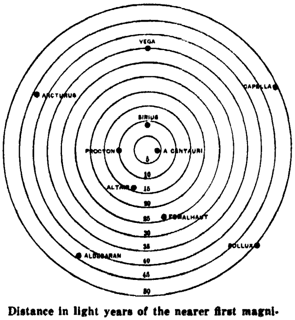
The first magnitude stars are such as appear the brightest to an observer on earth. The term does not mean their actual magnitude, either their mass, volume or inherent brilliancy. It refers only to the amount of light received from each of them at our terrestrial distance, the way they look, not the way they are. Very huge suns might be so distant or so dull as not even to be visible to the naked eye; and a fifth rate orb might be given rank among stars of the first magnitude, simply because it happens to be located comparatively near our own part of the universe.

In the table of first magnitude stars furnished herewith, there should be but little difficulty in committing to memory the names in their order, as well as the figures relating to their comparative brilliancy, their distance and their inherent light. If the southern luminaries, never seen in our northern latitudes, be omitted, the task is materially reduced. To know the facts concerning even these few stars is to know little enough concerning the universe, outside of our own miniature earth. One ought to have the ambition to extend his knowledge that far at the very least.

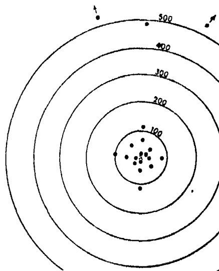
That we may comprehend the facts set before us in the table, a few remarks need to be made. We have already noted that, of the *entire* twenty, there are five never seen by us who dwell in the north. Of such immense importance are some of these, that it would be a great loss to omit them from our knowledge because they never show above our horizon. One of these is Canopus, next to Sirius in brilliancy, and 2½ times as bright as any other star seen in our north. While, as seen from earth, Canopus is second in the list, giving hardly more than half the glory of Sirius, in itself it is first in brilliancy, radiating an effulgence 10,000 times that of our superb sun. Nor are these figures mere estimates, but the result of scientific light measurements, from which the personal equation has been eliminated. Alpha Centauri, too, another southern star, third in the list, is of immense importance, as being the nearest star to earth that we know. Proximity explains its brilliance, for, in itself, it has the splendor of only two such suns as ours.

But, viewing the entire group of first magnitude stars, we see in them an illustration of the long-ago-uttered truth that "one star differeth from another star in glory." This is as true, as viewed from earth, as it is in their inherent light-possession Expressed in terms of magnitude, they run all the way from —1.6 in Sirius to 0.2 in Capella, 1.1 in Aldebaran and 1.3 in Regulus. Or, in comparisons *among* themselves, they run all the way from Sirius, regarded as 100, to Altair as 10 and Regulus as 7, the latter giving only 0.07 as much light as Sirius, yet grouped in the same class. In the matter of inherent brilliancy or absolute light-giving quality, there are immense differences, running from Alpha Centauri, with a light equal to twice that of our sun, to Altair, equal to 12 suns; to Pollux, equal to 125 suns; to Capella, equal to 800 suns; to Antares, 2,000 suns; Rigel, 4,000 suns; and Canopus, already mentioned as equaling more than 10,000

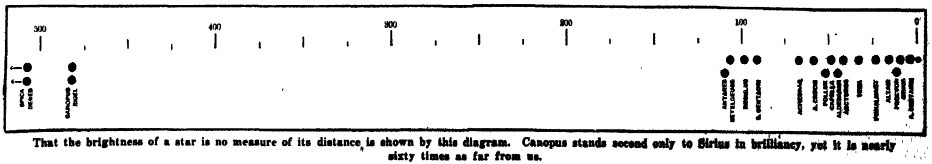
(*Concluded on page 296.*)



Distance in light years of the nearer first magnitude stars.



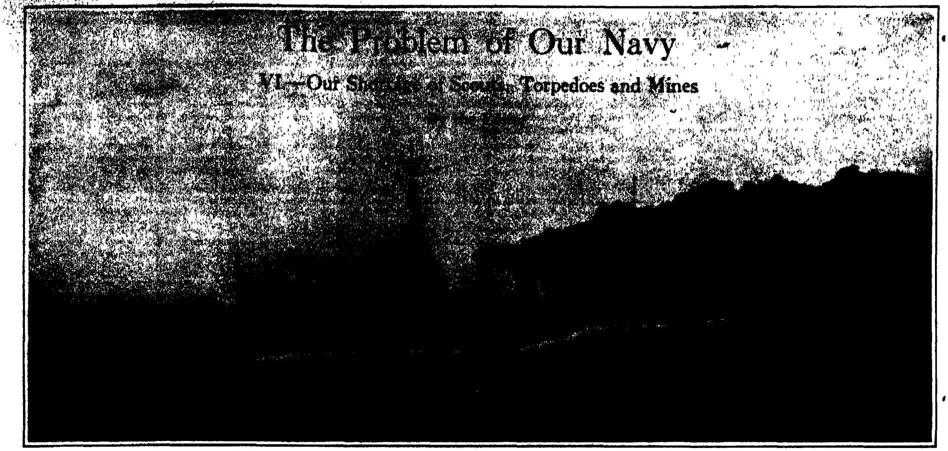
Gap of nearly four hundred light years separates the first magnitude stars.



That the brightness of a star is no measure of its distance is shown by this diagram. Canopus stands second only to Sirius in brilliancy, yet it is nearly sixty times as far from us.

The Problem of Our Navy

VI—Our Shortage of Scouts, Torpedoes and Mines



Copyright 1913 by Waterman.

IT is the duty—the patriotic duty—of the Press to present facts of grave national importance exactly as they are. To conceal defects, because their disclosure will destroy cherished delusions and wound the public pride, is to play traitor to a solemn trust. We offer no apology—nor will the public demand any -for drawing attention to the pressing needs of the American Navy and pointing out what must be done to bring it up to a definite standard of strength and efficiency.

We have shown that the Navy is deficient in battleships of the first class. Unfortunately, it is deficient, also, in those accessories which must be present in a certain definite proportion, if the battleship fleet is to realize its full efficiency.

Although the battleship will be called upon to play the star part in the great drama of a naval war, it must be supported by a strong cast, each filling a subordinate but most essential part. In this should be included scouts and hydro-aeroplanes for observation and information, destroyers and submarines for attack by the torpedo, vessels specially equipped for dropping mines athwart the enemy's course, fuel ships to provide a constant supply of coal and oil, ammunition ships to replenish the magazines, torpedo and mine depot ships, supply ships, repair ships, and last but not least, hospital ships

In all of these types, our battleship fleet is more or less deficient, and in most of them, fatally so. It is not our purpose now to enter into this question in great detail, but rather to confine ourselves to a consideration of three of the above types of accessories, in which we are so woefully deficient that the effectiveness of our first line of battle would be most seriously impaired, both in the strategy preceding an engagement and in the tactics which would be employed when the rival fleets were drawn up within range to fight it out with gun and torpedo.

WE HAVE THREE SCOUTS WHERE WE SHOULD HAVE THIRTY. The rôle of the scout is strategic Its work will be that of getting in touch with the enemy as quickly as possible and transmitting to the commander-in-chief the earliest possible news of his movements and probable intentions. The scout should be of high speed (not less than twenty-five to thirty knots), should possess large coal capacity, and should be of sufficient size, say from thirty-five hundred to five thousand tons, to enable it to maintain high speed in heavy weather. The scouts would be thrown far in the van of the battle fleet and disposed fan-wise over a wide area of the ocean, probably in a first and second line. The larger their numbers the closer will be their spacing, and the greater the difficulty for the enemy's scouts to pass through the screen and pick up information regarding the parent fleet.

At the present time, Great Britain possesses thirty-one scouts of from twenty-five to twenty-nine knots, Germany fourteen, and the United States three only, of twenty-four knots speed. At the present rate of construction, Germany in the year 1920, will have over thirty scouts and the United States, the way things are going at present, will have but three. Under such conditions, it would be necessary to use our destroyers for scouting purposes; but this would be to subject them to an arduous and trying service for which they are not primarily intended, a service which might impair their efficiency for the duty for which they are designed, namely, that of acting as a close protective screen around the battleship fleet. If the programme calling for the construction of six battleships per year in 1914, 1915, and 1916 be adopted, giving us a fleet of *forty-six battleships in 1920, the construction of scouts* should be taken up at an annual rate which would give us at least thirty of these vessels by the same date.

WE HAVE BUT ONE TORPEDO FOR EACH TORPEDO TUBE IN THE WHOLE FLEET Nowhere does our Navy appear so ill balanced as in the matter of our torpedo supply. As matters now stand, we have mounted in the battleships, cruisers, destroyers, and submarines about one thousand torpedo tubes; and as an ammunition supply for these tubes, we have available about one thousand torpedoes, or an average of one round per tube. We should have ten per tube This year the Bureau of Ordnance asked for the modest appropriation necessary to give us two rounds per tube. The House Naval Committee has refused it

The modern torpedo is so swift, accurate, and powerful that it promises to become a rival of the big gun as a weapon of attack; nevertheless, matters are in such a deplorable condition in our Navy that, in the event of a first-class fleet action, after firing the first round, our torpedo tubes would be entirely without ammunition!

To find a parallel for these amazing conditions we have to imagine an army taking the field with one cartridge in each soldier's rifle, or a fleet advancing to meet the enemy with only one projectile for each of its guns!

It will of course be understood that our supply of torpedoes is not evenly distributed throughout the fleet Some ships have more, some even less than one round per tube, but when we come to our fleet of destroyers, our principal arm in the torpedo service, we find, to give exact figures, that among one hundred and seventy-three tubes there are carried only one hundred and ninety-four torpedoes. This means that if our exceedingly fine flotilla of destroyers were engaged with the enemy, as soon as they had fired one round from their tubes they would be useless, either for attack or defense. The situation is so ridiculous and preposterous as to be scarcely believable

In the earlier years of the growth of our modern Navy, the development of our torpedo service went on very slowly, and we had but twelve torpedo boats in commission during the Spanish War Even such torpedo boats as we had were not used in that war for the purpose for which they were designed, and it was mainly due to the prominence given in the daily press to the fast destroyers owned by the Spanish, that in 1898 and 1899 Congress appropriated for sixteen destroyers and twenty-eight torpedoes In those days, the service was slow to appreciate the importance of the torpedo, and this apathy or distrust was shown in the fact that no torpedo tubes were fitted in the battleships appropriated for at that time. Later, we awoke to the fact that the torpedo was not only practicable, but that it was destined to play a leading part in future naval warfare, and it was finally decided to equip all first-class battleships with this weapon, and to make serious efforts to remedy the deficiency of torpedoes in the fleet.

About this time, the Bliss torpedo (an American product) was improved by the increase of the diameter from 18 inches to 21 inches, and by the application of heat to the air before introducing it to the engine The new turbine had a range of four thousand yards, and coincidently with the determination to install tubes on the new battleships, three hundred 21-inch torpedoes were contracted for, and one hundred 18-inch torpedoes were ordered for the new armored cruisers and submarine boats From that time on, the development of the torpedo in efficiency was rapid and better methods of heating, including the introduction of water into the superheater—a most important improvement which added about fifty per cent to the range of the torpedo—brought this weapon to its present truly marvelous speed, range, and accuracy To-day, the latest torpedo will run at a speed of twenty-eight knots for a distance of ten thousand yards, which is about the range at which modern battleship fleets will probably be engaged

No country has given such attention to its torpedo service as Germany. So greatly are the Germans impressed with the important rôle that the torpedo will play in future warfare, that they have directed more attention to this than to any other method of attack More money, relatively, is spent upon torpedo target practice and the various maneuvers incidental to the torpedo service, than upon any other branch of the German service The maneuvers carried out by the destroyer and submarine fleets are complicated, difficult, very dangerous, and are practically unremitting A German naval officer recently told the writer that it was believed in the German Navy that the great numerical superiority in battleships of the British, would, in the event of war, be largely off-set by the wonderful efficiency of the German torpedo service "They would win, of course," said he, "but it would be at a cost in capital ships so great as to relegate the British navy for the time being to the second rank "

Now, although our backwardness in the matter of torpedo supply may have been due in earlier years to lack of appreciation of its importance, for many years past, that is to say, from the time when the torpedo demonstrated its enormous value as a means of attack, our naval officers have urged upon the country the necessity for obtaining at once an ample supply of this weapon, by purchase abroad, by encouraging its construction by private firms, and by an increase in the capacity of the Government torpedo factory

The present dangerous and positively ridiculous conditions of one round only per tube is chargeable to Congress and to Congress alone If the moneys asked for had been appropriated, we should not now find ourselves in the possession of a fleet of first class destroyers that is practically without ammunition

It takes about one year to build a torpedo, and the cost of each is about $5,000 We shall need to secure within the next ten years from all available sources at least ten thousand torpedoes, and these will cost in the neighborhood of fifty million dollars The necessary number could be obtained, if the Bureau of Ordnance were authorized to provide for securing the needed supply before the end of the fiscal year 1924, an annual appropriation of $5,000,000 being made for that purpose

We spend $180,000,000 a year in pensions, yet we begrudge spending one thirty-sixth of that sum for rendering serviceable our fine destroyer and submarine fleets, upon which we have expended some $50,000,000!

There are three possible sources of supply first, the foreign manufacturer, second, the domestic manufacturer; and third, the Government factory Since the supply to be obtained by purchase from abroad is uncertain, and liable to be cut off altogether it should be the policy of the Government, by liberal patronage, to encourage the private manufacturers to enlarge their plants, and it should also make the necessary enlargements of its own torpedo factory at Newport.

OUR SHORTAGE OF MINES AND MINING EQUIPMENT. One of the most important lessons taught by the Russia-Japanese war was that of the deadly efficiency of the mine, whether floating or anchored. Those of us who followed the events of that war have not forgotten the terrific blow struck at the Japanese battleship fleet by the floating mines which sent the battleships "Hatsuse" and "Yashima" to the bottom; or the tragic loss by the same means of attack when the "Petropavlovsk" went down in two minutes, carrying with her Russia's ablest officer, Admiral Makaroff. Time and again the ships of the contending fleets bumped into the floating mines which had been strewn in their way by the enemy, and, if they were not sunk, they were so seriously crippled as to be put entirely out of action.

The lessons of that war have been laid well to heart by the great naval powers; and the mining service has been developed to such a degree of efficiency that it will form one of the decisive factors in the tactics of future naval operations. A most important use of this weapon will be made by the fast scout and destroyer flotillas in fleet engagements. The maneuver will consist in steaming swiftly across the head of the enemy's battleship column and dropping a number of mines across his course. This will necessitate his changing course, either toward or from the fleet with which he is engaged; and, in either case, he will be placed at a great disadvantage as regards his own and the enemy's gun fire—as regards his own, because he will be more or less in the head-on position, and his fire will be curtailed; as regards the enemy's attack, because he will be exposed to a raking fire in which the hits will be more frequent and more destructive

By way of illustrating the value of floating mines and fully equipped mining ships, specially designed for dropping them in great numbers and swiftly over a chosen stretch of water, we close this chapter with a description of the loss of the Japanese battleship "Hatsuse" during the blockade of Port Arthur. The facts were given to the writer by an eye witness, Captain, now Admiral, Von Essen of the Russian navy.

The Russians had determined by instrumental observations that the Japanese blockading fleet steamed during the daytime back and forth in front of the harbor on a pre-determined course, laid apparently between two landmarks. Accordingly, one night they sent out their mine-laying ship and dropped a string of mines, or rather two or three of them, across the Japanese course as thus determined. The next morning, a group of naval and military officers gathered, at dawn, on one of the lofty hills surrounding Port Arthur, and saw the Japanese fleet come up out of the offing and proceed to steam on its regular route The "Hatsuse" was at the head of the column; and when she entered the mine field, a huge column of water was seen to rise at her bow, and in a few minutes time this, one of the finest ships in the Japanese fleet, had disappeared!

This terrific engine of warfare destroyed or seriously crippled during the Japanese war more battleships and cruisers than the torpedo. Yet it is a fact that our supply of mines is even smaller than our torpedo supply, which, as we have seen, amounts to only one round per torpedo tube. This most serious state of affairs is not chargeable to the Navy Department, it is due to the failure of Congress in past years to listen to the warning of its naval advisers, and its refusal to make the necessary appropriations.

Gravitation and the End of the World

By John W. N. Sullivan

THE law of gravitation, as formulated by Newton, is one of the greatest generalizations in the history of science. The magnificent structure of modern dynamical astronomy rests upon this law as its basis, and the variety and grandeur of the phenomena it has proved itself able to explain, have raised it to a level of importance, and invested it with a degree of certitude, which scarcely any other generalization in science possesses to the same degree. But, in spite of this, doubts have from time to time arisen whether the law, in the form in which Newton left it, is quite exact. According to Newton, the attraction between two bodies depends upon the masses of the bodies, and varies inversely as the square of the distance between them. It has been suggested that the inverse square law is not quite accurate, and also that the relative velocities of the bodies concerned may affect the force of attraction between them. These hypotheses have been suggested by the fact that certain minor phenomena in astronomy are not satisfactorily accounted for by Newton's law. There are certain slight motions of Mercury, Mars, Venus, the Moon, and Encke's comet which exhibit discrepancies with the theoretical motions calculated on the basis of the strictly Newtonian form of the law of gravitation.

It would appear that a revision of the law has become necessary. It is highly probable that the relative velocities of bodies do affect the force of attraction between them. In fact, on the modern electronic view of the constitution of matter, the mass of a body is affected by its velocity; and the force required to change its motion depends upon the relative directions of the force acting, and the velocity of the body. So that even if the gravitational force is directly proportional to the masses, the masses themselves depend to some extent upon their relative velocities. It is possible that this is the direction in which an explanation is to be sought, of the anomalies mentioned above. But the chief difficulty about the law of gravitation is the mere fact of its existence. The aim of modern physics is to explain all material phenomena in terms of electrons and ether, but the attempt to account for gravitation in this way is attended by the greatest difficulties. We have learned to regard electricity, light and heat as forms of radiant energy, all of which are transmitted at the same velocity, but it seems almost impossible to account for gravitation along these lines. One thing which must be borne in mind is that gravitational forces are extremely minute in comparison with electrical forces, so that on an electric theory of the universe, gravitational forces may be treated as in the nature of residual effects. As illustrating the relative minuteness of gravitational forces, we may mention that if the opposite electricities were extracted from a milligramme of water, and given to two spheres one mile apart, those two spheres would attract each other with a force equal to the weight of twelve tons. In the older etheric theories, the ether was treated as an elastic solid, and in the equations to wave motion in an elastic solid we have a term which admits of compressional waves, as distinguished from the transverse waves which we know to constitute light. This compressional wave could have any velocity we please. Laplace showed that if gravitation has a finite velocity of propagation, its speed must be much greater than that of light, and he assigned as a minimum speed for gravitation a velocity one hundred million times that of light. More recent work has reduced this estimate, but it is still considered that the speed of propagation must be in the neighborhood of a million times that of light. From this point of view, compressional waves in the ether would offer no difficulty, but, as the result of a mathematical investigation by Larmor, it appears that such a theory would lead to a repulsion between bodies instead of an attraction, and a repulsion, moreover, which does not obey the inverse square law.

Lorentz endeavored to explain gravitation by assuming that in matter, considered as built up by negative and positive electrons, the attraction between a pair of electrons of unlike sign exceeds the repulsion between a pair of electrons of like sign. But on this hypothesis, the gravitational action between two bodies should vary with the nature of the intervening medium to an extent which should be easily observable, whereas a striking feature about the gravitational attraction between two bodies is that it seems to be quite independent of the nature of the medium between them. Laplace has shown that the attraction of a molecule at the center of the earth, upon a molecule at the surface, could not, in accordance with the known agreement of Lunar theory with the results of observation, be diminished by as much as one part in a million, owing to absorption in its passage through the earth.

A remarkable consequence of assuming gravitation to be an action transmitted by the ether was pointed out by Maxwell. He showed that this assumption necessarily leads to the conclusion that every portion of the ether possesses an enormous intrinsic energy, and that the presence of material bodies so influences the medium as to diminish this energy whenever there is resultant gravitational attraction. Sir Oliver Lodge estimates that the value of the intrinsic energy of the ether, when in the undisturbed condition, is of the order of 10^{33} ergs per cubic centimeter, and it is very probable that this estimate is much too low. It is interesting to see whether a maximum limit can be assigned to the gravitational force in the universe. If the number of bodies in our ethereal universe is indefinitely great, it has been pointed out by Neumann, and later by Seeliger, that the force of gravitation may become indeterminate at certain points, and even infinite. It has been attempted, but without success, to find some modification of Newton's law which would obviate this difficulty without coming into conflict with the results of astronomical observation. The difficulty may be overcome if we adopt the very remarkable hypothesis of Föppl, by postulating the existence of negative, as well as positive, masses in the universe. If the sum of such negative masses were assumed numerically equal to the sum of the positive masses, all the lines of gravitation force, like those of electric force, would start from positive masses and end on negative masses. Moreover, negative masses would attract one another according to the same law as positive masses, and in our present state of knowledge it would be impossible to distinguish a system of negative masses from one of positive masses. Of course, a system of negative masses would repel a system of positive masses in the neighborhood, but at the present time all such actions, owing to the great distances apart, assumed in consequence of these mutual repulsions, would probably be too feeble for observation.

Schuster has also pointed out that the existence of such negative masses would afford an explanation of the origin of the rotational velocity of the solar and other stellar systems.

The electromagnetic scheme does not seem sufficient to explain gravitation, but before considering some of the modern theories which have been proposed, we must deal briefly with the celebrated hypothesis of Le Sage, which was propounded in 1750, and recently resuscitated for a time by Kelvin. Le Sage assumed that all space is being constantly traversed by shoals of minute particles which subject all bodies to a state of continual bombardment. An isolated body is bombarded equally on all sides, and so is subject to no resultant force. But if two bodies are near together they exert a mutual screening action, and the result is a force tending to urge them together. Such is the essential theory, and it can be worked out so as to agree with Newton's law of gravitation. But to do this necessitates the assumption that an enormous amount of energy is being continually contributed to the universe by these corpuscles, and Maxwell showed that the heat so developed would be sufficient to volatilize the entire universe in a few moments. He remarks dryly that as a matter of experimental observation the universe is not volatilized and hence the theory cannot be true.

At the present time, in order to cope with the difficulties raised by the existence of the law of gravitation, scientific men have been compelled to assume that our ethereal universe only forms a portion of a greater universe, and to contemplate definite, physical actions extending beyond the extremest limits of that ether which fills all that we know as space. This assumption seems to be necessary, and indeed, one theory conceives our space as being merely the three-dimensional boundary between two four-dimensional universes. Such strange hypotheses would have been ridiculed a few years ago, but modern investigations in science have taught us that we are only touching the fringe of the unexplored possibilities of nature, and that we live in a universe wonderful beyond all our dreams.

From 1863 to 1875, Bjerknes published some investigations dealing with the problem of pulsations of two spheres in a fluid, pulsations being defined as consisting of periodic changes of volumes, just as vibrations consist of periodic changes of position. It appears that such pulsating spheres act on one another with a force whose principal part varies inversely as the square of the distance, and this applies to slightly compressible, as well as to incompressible, fluids. It occurred to Prof. Hicks that this method might be applied to account for gravitation, the electrons being the pulsating bodies, and the ether the fluid medium in which they are immersed. In order that the members of such a system may mutually attract one another, it is necessary that the phases of pulsation for the various electrons should not differ by more than 90 degrees. If we do not restrict the phases in this way, then the electrons will not necessarily attract one another. It would be possible for the bodies of one star system to attract those of a second, repel those of a third, and to exert no action whatever on members of a fourth system. This theory therefore provides for the existence of both positive and negative masses, and also for the existence of neutral bodies. It would be quite possible for bodies neutral to our system to be driven into its vicinity by repulsion from other systems, and thus the theory suggests the possible existence of weightless matter within the limits of our system. Sir Joseph Larmor suggests that "we may imagine the pulsation to have been applied initially over the outside boundary of the ethereal universe, and thence instantaneously communicated throughout the incompressible medium to the only places that can respond to it, the vacuous nuclei of the electrons; and we can even imagine the pulsations thus established as spontaneously keeping time and phase ever after, when the exciting cause which established this harmony has been discontinued."

It has been shown mathematically that in order that the law of attraction should reign throughout our universe, the waves impressed on the ether from that unknown and inaccessible region beyond our universe would have to have a wave length more than twice as long as the greatest distance for which Newton's law of gravitation is known by astronomical observation to hold good. The velocity of these compressional waves is taken as being 2.19 by 10^{27} C. G. S. That is to say, a light wave traveling at a speed of about 186,000 miles a second would take more than two thousand million years to travel the distance traversed by a compression wave in a second. The energy conveyed by these enormous waves is on the same gigantic scale as their velocity and wavelength. The energy passing in a second across an area of a square centimeter at right angles to the direction of transmission has the enormous value of 3.4 by 10^{41} ergs, an amount of energy exceeding by many million times the sun's entire store of available heat.

Another hypothesis which has been adopted to explain gravitation is to assume the existence of a steady hydrostatic pressure transmitted through the ether. Kelvin showed that when a steady or twistless flow is once estab-

[illegible] through one or more apertures in a movable solid immersed in a liquid, it will continue unchanged forever, but that if there are two or more such solids within a finite region, mutual forces will arise in consequence of the flow. A *steady flow of ether*, either into or out of every electron in a gravitating system of bodies, would give rise to forces of attraction between them, varying inversely as the square of the distance. The theory explains Newton's law of gravitation, and also provides for the existence of negative masses. In order to avoid the conception of the continual destruction and creation of ether, we must, in accounting for this etheric flow, assume either a slow, steady expansion or contraction of the electrons, or a flow of ether through every electron between our universe and a greater universe of which it forms a part. Since every electron must lie on the boundary of this greater universe, in the latter alternative, this greater universe must be a four-dimensional universe. This conception may be repugnant to some minds, but the first alternative also leads us to sufficiently startling conclusions. Schott has worked out mathematically the hypothesis of expanding electrons, in reality assuming a slow pulsation of extremely long period, as we can hardly suppose an electron to expand indefinitely. Dr. Schott suggests a rate of expansion which would double the size of an electron in three hundred million years. It would be necessary to ascribe to the ether a density of 10^{100} times that of water. On this theory there will come a time when the expansion of the electrons gives place to contraction, but there would be a sensible period when neither expansion nor contraction was experienced. This would mean the cessation of all gravitational attraction, and of all cohesion in bodies, in other words, a catastrophic upheaval of the entire material universe.

A Vindication of Adjustable Wings

By Carl Dienstbach

THE "Paul Schmidt" biplane, which the writer hailed as a decisive step ahead in the development of aviation, when it made its appearance in the recent aeronautical "salon" at Paris, has since furnished convincing proof of the correctness of his assertions. It has established height records of 7,000 feet with five and of 5,300 feet with six passengers. Thus it has conclusively set at rest the principal and natural objection of the constructor of the old type of aeroplane with wings and fuselage, the objection that an adjustable angle between wings and fuselage is not "practical" because the structure would be weakened. Flying and landing with such a load put the structural solidity of the machine to the most severe test possible, and, incidentally, showed how little the added mechanism increased its weight.

It has equally proved the truth of the aerodynamical and aerodromical advantages claimed for wings of variable angle, because the phenomenal carrying capacity directly resulted from this arrangement.

The pilot, Garraix, started (on January 31st, at Chartres) with the angle between propeller thrust and wing chord adjusted to four degrees; when at 3,000 feet he could not climb higher with his load, he increased this angle to six, and, to attain 6,000 feet, to eight degrees At the maximum altitude of 5,300, it was nine degrees. (The maximum angle of adjustment is 12 degrees, but this produces not the greatest absolute lift of the machine, but only the greatest lift at slow speed, for starting and landing and the "airhole." With the immense surplus lift of this machine as proved by these weight-carrying tests, it can, with normal load, be rightly acclaimed as exceptionally safe. Incidentally, the way this remarkable performance (with five up to 5,300 feet it took only 37 minutes) was accomplished, corroborates the writer's assertions as to how and why it was possible to establish a height record with a "baby" Wright racer. The only improvement still needed to realize the full safety advantages of the "Paul Schmidt" is in providing a mechanism which by power may change the inclination of the wings in case of danger as quickly and gradedly as a rudder is changed by hand—no very difficult task for an inventor. It is to be hoped that the prejudice in favor of directly-driven, relatively small propellers and of non-adjustable propellers may likewise soon be relegated, like the ancient prejudice in favor of muzzle-loading rifles, to those begotten by inventive laziness.

Wireless in the Antarctic

THE Austrian expedition under Dr. König, which is to sail for the Antarctic this year, proposes to establish a wireless telegraph station at its base in the Weddell Sea region. On its way south the expedition will erect an auxiliary wireless station in South Georgia. Thus the explorers hope to keep more or less constantly in touch with the world, as Dr. Douglas Mawson has done, on the opposite side of the Antarctic continent, by means of his two wireless stations—one in Adélie Land, and one at Macquarie Island.

Bad Orthography on Films

To the Editor of the SCIENTIFIC AMERICAN:

I cannot understand why Portuguese, or any other foreign language, could not be written on moving picture films with the same care and correctness as on some catalogues sent out by important firms of the United States. I've noticed that almost all film makers take very little care in producing a well written film. It would be ten times better not to attempt translation than to fill a drama or a tragedy with such letters as will provoke laughter owing to its absolute lack of orthography.

Another great defect is the duration of written matter on the screen. Some are too short while others tire the audience. These faults are very easily remedied

Joinville, Brazil. R W T

[Our correspondent is unquestionably correct in his contention. Here in New York the same bad spelling is noticeable. Some of the printed matter exhibited on films which have been imported from France are crude translations, obviously incorrect in some cases and unidiomatic in others As for the amount of reading matter which is offered to the public by way of explanation, it must be stated that the tendency nowadays is to reduce it to its lowest terms. Even the explanatory letter which at one time seemed almost inevitable is now encountered only occasionally. Gradually it is recognized that the film must employ its own technique, in other words that photography is not literature.—EDITOR.]

A Letter from an Old Reader

To the Editor of the SCIENTIFIC AMERICAN:

It may interest you to know that I was introduced to the SCIENTIFIC AMERICAN in 1858. It was the "Golden Key" that opened Nature's wonders to my youthful eyes, as explained to me through my father's evening readings from your journal, and who was your subscriber, along about that time, and up to 1860-61, and again after his return from "The Front."

As I remember this publication of those long ago days it was about 8 inches by 12 inches and four pages I am not positive, but it was somewhat small. I recall an incident in my life in which the SCIENTIFIC AMERICAN was a factor. In the autumn of 1858 Donati's comet was a most brilliant object in the western sky, the nucleus pointing toward the horizon, its immense tail flaming away toward the zenith. The SCIENTIFIC AMERICAN was loaded with all kinds of speculations about the big visitor bumping the earth, and of course it got my youthful mind so full of fearful ideas that I was ready to explode on the least provocation Well, one afternoon a tremendous wind and rain came tearing out of the northwest, but as our dwelling was located on the side of a big hill I could not see the approaching storm, but the roar was enough. I shouted to my mother, "Look out, here comes the comet!" I got down on my knees and put in the hottest five minutes of prayer that ever a boy did The supplication was opened in our door-yard, but the amen occurred in an adjoining cornfield. Like the darky preacher treed by a bear: "Oh, Lord, if you is going to help anybody, don't you help the bear" I was positive that the infernal thing had punched a hole in the adjoining scenery somewhere.

I always laid that "blow out" to the SCIENTIFIC AMERICAN. CHARLES W HANSEN

Erie, Pa.

Snow Removal

To the Editor of the SCIENTIFIC AMERICAN:

In your issue of March 14th, I notice what Mr P A Hutchinson of New York has to say regarding snow removal. I fully agree with him when he says: "A power shovel, mounted on a motor truck, would seem not difficult to invent."

And further, I wish to say that one on similar lines was recently invented, and a notice of that fact mailed to Commissioners of the Departments of Street Cleaning in several large cities in this country and Canada. Each was asked if there was a demand for a machine of this kind. All answered in the affirmative, except Mr. Fetherston of New York city.

His answer follows, under date, February 23rd, 1914:

"Referring to your letter of the 20th instant, the Commissioner directs me to say that there is no demand for a loading machine. The greatest difficulty is to secure a proper number of carts to carry off the snow."

A. B. MCSTAG, *Secretary to the Commissioner.*

Doubtless if this had been called to Mr. Fetherston's attention at a time when he was not "snowed under" with work it would have appealed to him as quickly as it did to the others. If it takes one minute to load a wagon with a power shovel, and ten minutes to load one with hand shovels, it is quite obvious that the former could be kept on the move almost continually, while the second could not, thereby greatly increasing the number of loads in a given time.

I also think if dump cars were used on the street car tracks for hauling, as Mr. Hutchinson has suggested, combined with a practical power shovel, the problem of snow removal would be solved to the satisfaction of taxpayers and the public in general

Shelburne Falls, Mass F H BASSETT.

Bacterial versus Inorganic Fertilizers

To the Editor of the SCIENTIFIC AMERICAN:

I have read with great interest the recent discussion in your paper of "Bacterial versus Inorganic Fertilizers." Mr W. H. Bowker's letter shows that he is evidently not acquainted with modern agricultural thought and practice The growth of the fertilizer industry is no more of an index to its true worth than would be the development of the art of patent medicine Such things may flourish through the ignorance of customers and the desire to make money

Mr Davis, in his letter of January 24th, states the facts so clearly that there can be no room for argument

The modern farmer is a business man, cultivating food for man in a more or less finished form, and one of his great problems is that of keeping up the fertility of his soil. In doing this his greatest undertaking consists in keeping up its humus content, this being necessary to make plant food available for holding soil in good tilth and preserving its moisture-retaining powers. His nitrogen supply comes from his forage crops, alfalfa, clover, peas, vetches, etc. It is a by-product, and a steady and sure way of obtaining it is one of no cost and not at all a haphazardous matter

Mr. Bowker thinks that beginners would be satisfied if they could be grown as easily as weeds Well, they can. Sweet clover is one of the best, and is coming into greater use every year, although it was for a long time regarded as a mere weed There are hundreds of acres of alfalfa that have stood for over twenty years in a country subject to much freezing and thawing, with a recorded temperature range of from − 56 deg. to 110 deg. Fahr Mineral nitrogen may have some use in the building up of our worn out Eastern soils. Their condition is not a result of scientific agriculture, but because of the burning up of their humus, by mismanagement and the misuse of commercial fertilizers.

By all means use all the by-product nitrogen possible. This is conservation; but it is not conservation to make something by an expensive mechanical process that can be obtained as a by-product at an outlay neither in cash nor in labor INGOLL BIRKELAND

Judith Gap, Montana.

To the Editor of the SCIENTIFIC AMERICAN

As bearing on the subject of "Bacterial versus Inorganic Fertilizers," discussed by R W Davis of Moline, Ill, in your issue of the 24th of January, and by W H. Bowker of Boston, in your issue of February 14th, I am taking the liberty of quoting a paragraph from Bulletin 145, issued by the South Carolina Agricultural Experiment Station of Clemson Agricultural College, designated "Fertilizer Experiments With Cotton," which is as follows

> " We also note that where lime was applied to plots on which cow peas and vetch were grown there appears to have been a much greater accumulation of nitrogen in the soil, for these plots so treated have not responded to the use of nitrates, that is, they have given just as large yields where no nitrate was applied These experiments indicate that lime not only assists the legumes in accumulating nitrates in large amounts in the soil, but assists in some way in keeping this nitrogen from being washed out of the soil during the winter—how we are not yet prepared to say "

Since legumes that are not inoculated "fix" no atmospheric nitrogen, this is good evidence that it is possible to store in the soil through inoculated leguminous crops, where the land is limed, all the nitrogen required by the succeeding crop for its normal and continuous growth.

I would like to add that Clemson College and its fine staff of county agents advocate the feeding of the crops to farm animals so that the manure may be returned to the soil, providing not only additional nitrogen, but all the phosphorus and potash removed by the crop from the soil, with slight loss, and also a host of other bacteria of the non-symbiotic varieties, some of which also "fix" atmospheric nitrogen, and others which make insoluble compounds into available plant food

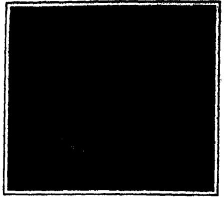
How the Scientists Are Studying the Aeroplane

Institutes of Aerial Engineering and Their Work

By Paul Béjeuhr



Air current lines as determined by Riabouchinsky.

THOUGH the first beginnings of successful aerial navigation are only a few years old, nearly all civilized countries already possess research institutes for the scientific investigation of problems connected with this art. This country still uses mainly the installations provided by S. Pierpont Langley at the Smithsonian Institution of Washington, though since the death of this eminent man, a certain stagnation in aeronautical research seems to have taken place. This is the more to be regretted as Langley's rotation experiments on the air resistance of all kinds of models had been developed to a remarkable degree of perfection. It will be remembered that in connection with these experiments a steam engine, through the intermediary of a bevel-gear drive arranged below the floor, served to actuate the rotating arm which also carried all the measuring instruments The disk to be tested was fitted to a double lever pivoted round the end of the rotating arm. Under the action of the air resistance, one arm of the double lever would undergo a certain deflection recorded automatically by a style fitted to the other arm, which was kept in a central position by a system of four springs exerting a tension just equivalent to the air resistance. An electromagnet only allowed contact between the paper and style after the disk had reached a position of equilibrium, thus preventing any friction losses. The same apparatus, by a convenient combination with a falling-disk machine, a propeller testing outfit, a movable carriage, etc., was also used for other experiments. Furthermore, Langley was the first to show as far back as in May, 1896, the practicability of mechanical aeroplane models. Encouraged by these experiments, Langley, in 1903, prepared to launch a manned aeroplane designed on the same principles, but his extensive preliminary work was cut short by the aeroplane falling into the water and being entirely disabled.

In England, there are, apart from Lanchester's investigations, conducted at the National Physical Laboratory, the installations of the National Physical Laboratory at Teddington, Middlesex, where some very important work has been done. The testing plant of this laboratory is based on Froude's model tests and comprises an air channel through which a circulating current of air is drawn by a sirocco fan. The measuring channel proper is arranged in the middle, the air being allowed to return at the outside, which of course complicates the arrangement. Vertical intermediate walls and sieves serve to ensure a uniform direction and distribution of the air throughout the cross-section of the channel. The object to be examined having been introduced through a slot, is suspended from one end of a double lever, the other end of which allows the buoyancy and resistance to be gaged. These tests, made at a wind velocity of 20 meters per second, showed the buoyancy due to air resistance to reach a maixmum with an inclination of about 7 degrees The resistance coefficients of vibrating wires were also tested and found to be practically the same as with fixed wires. A rotary outfit built up of light steel tubes is used for the examination of propeller models. Another very useful arrangement is the aeroplane motor-testing plant. The motor to be tested is braked electrically by means of a dynamo, wh

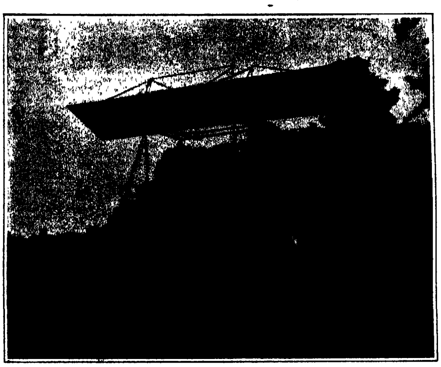
Lindenburg Institute air propeller testing apparatus.

being submitted over a cross-section of 1,200 square meters to an air current of up to 35 kilometers per hour, thus imitating, as closely as possible, the conditions of actual work. A similar motor-testing plant has, by the way, been installed by the *Luftschiffbau-Zeppelin-Gesellschaft* at *Friedrichshafen*, Germany. Another noteworthy arrangement is a lattice tower about 65 feet in height, with a rotatable platform for gaging air pressures on disks in a natural wind. These experiments have for instance shown a considerable increase in the intensity of the wind at a given place during 5 minutes, whereas no such increase could be observed at 137 meters distance. Arrangements for hydrodynamical tests have been made to supplement the former; the models used in this connection are at rest while the water current moves at speeds as uniform as possible throughout the cross-section.

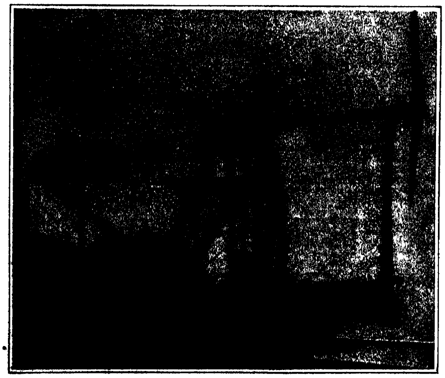
Another remarkable English installation is the large air propeller-testing plant at Messrs. Vickers Sons & Maxim, Ltd., works at Barrow-in-Furness. This comprises a rotating lever 50 meters in length, the measuring arm of which, 33 meters in radius, turns in ball bearings round a huge cast-iron pillar, whereas the other arm carries the counterweight. Above the pillar there is the observer's cabin, where, in addition to any necessary instruments, a 100 horse-power electromotor for use in driving the propeller has been installed. Thus, this rotating outfit is only actuated by the air propeller itself. Thrusts are recorded by a slight axial displacement of the propeller shaft with the aid of angular transmitting levers, and the work expended is determined by examining the electromotor. This testing plant shows the advantage of eliminating the effects of wind.

Especially numerous are the aerodynamical institutes in France, as might be expected in a country which takes so eminent a share in the development of aerial engineering. Those created by M. Eiffel—mainly for investigating the laws of air resistance—are especially well known. After performing extensive falling tests from the lowest story but one of the Eiffel Tower, he erected a special aerodynamical laboratory on the Champs-de-Mars which mainly contains an air channel where tests on immovable models with artificial air currents are made. A sirocco ventilator, 1.75 meters in diameter, draws in some air from the laboratory hall, conveying it round its sides into a larger hall where it is allowed to calm down, in order, eventually, through a system of channels, to return, at the proper speed, into the laboratory hall. Between the air outlet and the suction tube there is the experimental room proper. The disks or other models are suspended from a special balance which, by slight adjustment, allows the resultant of the buoyancy and resistance to be ascertained. This balance is installed on a bridge above the laboratory room proper. The well-known steam-turbine constructor, M. Rateau, has installed a similar plant for the testing of models in a moving air current, in connection with which the air is likewise allowed to pass freely through the laboratory room proper, whereas, in all other testing plants (Prandtl, Reissner, Riabouchinsky) there is always an air current moving through a closed channel, which can therefore not be entered during tests. The most recent creation of France is the Institut Aérotechnique of the Paris University at St. Cyr, founded by Henri Deutsch de la Meurthe. This comprises, on a large plot beside the main building, a special rotary test-plant shed and a straight track 1,360 meters in length, which will be used for resistance tests on disks placed in a natural air current, as well as for the testing of propellers. The main building comprises a huge exhibition hall which will at the same time be used for all kinds of experiments, and to this are connected on both sides the laboratories and research rooms, while the testing machinery takes up one of the transversal sides. The testing truck, on the straight experimental track, is propelled at a speed of up to 25 meters per second, by electro-motors deriving their current from rails running alongside the track, and as these motors are steered from the roof of the Institute, the trucks can be run unmanned. The traveling speed is recorded by a chronograph and tachograph, and the resistance thrusts on the surfaces are tested by hydraulic measuring instruments actuating special recording manometers.

St. Cyr testing car for use in resistance and propeller tests.



Prof. Donat Banki's arrangement for the testing of monoplanes.



Prandtl transportable testing plant, the carriage being driven by the propeller itself.

Reference should also be made to the tests made by Dr. Armand de Gramont, Duke of Guiche, which mainly relate to the distribution of pressures on disks in a natural air current. The disks used in this connection were fixed to an outfit installed above an automobile traveling at a high speed on a good forest road, where practically any side wind was kept out.

In Italy should be mentioned the arrangements provided by the *Brigata specialisti* on plans by Captains Crocco and Ricaldoni, which are continually being extended. The wind channel used in this connection shows the special feature that measurements are made just in front of its mouth, after which the air is allowed to escape into the open. The fan 2.5 meters in diameter has thus always to draw in a new supply of air; it is operated by a 30 horse-power electro-motor, and imparts to the air current a speed intermediary between 2 and 29 meters per second. The air current at first enters a large iron tank where it is allowed to calm down. Having thus been freed from any eddies, it penetrates through a tube one meter square into the laboratory-room proper. A traveling frame from which the models are suspended is moved in front of this mouth. An improved Renard dynamometrical balance is used to gage the work induced in the air propeller, independent of any losses in the driving motor and transmission devices. This balance comprises a light frame in the center of which the propeller to be tested is so suspended that the air current undergoes no deflection. Any motion in the direction of the air current is compensated by a proper weight put on a vertical arm of the frame. The propeller obstruction (due to its torque) manifests itself by an inclination of the whole frame and is likewise compensated by weights. The results obtained in connection with the testing of dirigibles by means of special models suspended in a Cardan frame have been of especial value. A large tank, which is to be replaced by a canal 188 meters in length, 3 meters in width and 2 meters in depth, is used for tests on moving models in resting water.

Extensive tests have also been made on propellers (at first on models and afterward on actual propellers) either in a stationary plant or on a gliding boat.

In Russia there are at present three aerodynamical institutes, both the University and Technical High School of Moscow being connected with testing plants, while a third institute at Koutchino is conducted by its founder, Riabouchinsky. The Institute of Moscow University has been in existence since 1902, and comprises two minor air channels, one of which is 1.6 meters in diameter and admits of an air speed of 20 meters per second. Into this channel is introduced a propeller testing apparatus, in connection with which the electro-motor, direct-coupled to the propeller, is arranged in a light frame free to rotate as a simple lever round a point in the channel wall, its weight being compensated by proper counterweights. The propeller thrust manifests itself in the same sense, and is likewise determined by weights. The Institute also comprises apparatus for falling tests and experiments on the escape of highly-compressed air. Of the aerodynamical arrangements of the Technical High School there should be mentioned a special measuring channel designed for investigating the air resistance of plates the length of which is very large as compared with the width. The arrangements installed by Riabouchinsky are of the most varied description and relate to all the different branches of aerial navigation. Measurements in a moving air current are made in a huge air channel through which the air is drawn, not from the room itself, but from a larger cylinder which likewise serves to calm the motion of the air. In connection with model tests up to diameters of 0.5 meter, a modified Renard double balance is used. In the case of large propellers (4 to 10 meters in diameter), a somewhat different arrangement is employed, the propeller working in an upward direction against the free air stratum, thus exerting a downward thrust which is transmitted by a step bearing to a recording style. A set of beveled wheels is used for measuring the induced work.

Experiments here have been made mainly on the influence exerted by the number of vanes on the efficiency of a propeller; up to what limits the projection of the vanes on the surface of the propeller circle can be increased, and similar problems. Most interesting resistance tests on disks in flowing water were made in a little river in the neighborhood of the Institute. Especially striking comparative tests have been conducted on the Ahlborn current lines in air, by means of a square plate lined with black paper on which lycopodium powder was spread uniformly.

In Germany there are, in addition to the research laboratories of the large aerial navigation companies and aeroplane-building firms (Testing Department of the Corps of Engineers, Zeppelin Company, Parseval Company, Siemens-Schuckert Werke, Messrs. Lanz, etc.), the Testing Institute of Professors H. Junkers and H. Reissner at the Aix-la-Chapelle Technical High School, the Aerodynamical Laboratory at Lindenberg, and the Aerodynamical Testing Plant of the Motor Airship Study Company at Göttingen.

The Aerodynamical Laboratory of the Aix-la-Chapelle Technical High School comprises an air channel through which the air is drawn by means of a centrifugal fan. In opposition to the Göttingen plant, where the same air current is used in continual operation, a new supply of air is always drawn in, thus allowing higher velocities (so far, up to 30 meters per second) to be reached with the same motor output, while insuring a great homogeneity, though these advantages are of course offset by the dependence on actual wind conditions. This plant has so far been mainly used for propeller tests.

The Lindenberg Aerodynamical Laboratory likewise is mainly intended for use in testing air propellers, no models but actual propellers being used and, as far as possible, under the natural conditions they will be called upon to work. The testing machine is operated by a 34 horse-power electro-motor through a belt and beveled wheels, and produces 40 to 600 revolutions of the propeller per minute. A hollow shaft and an axle rotating inside allow the two propellers to be driven in opposite directions. The propeller thrust can be compensated by means of step bearings, levers and weights, and the induced work is gaged hydraulically. A large number of systematical determinations have been made by means of this outfit, which yields especially valuable information on the working of lifting propellers. Experiments with manned and unmanned kites made at Lindenberg exceed in point of accuracy any work of a similar kind

The model testing plant erected at Göttingen, on plans by Prof. Prandtl, mainly comprises a closed endless channel of square cross-section (2 meters square), inside of which the air is set in continual motion by a ventilating fan A special regulator allows any wind velocity to be maintained irrespective of fluctuations in the mains feeding the electro-motor A system of tubes of decreasing diameters distributes the air current uniformly over the whole cross-section, and a sieve with fine meshes eliminates any eddies Resistances are determined by means of balances and sliding weights, and the distribution of pressures is read by means of micromanometers The velocity of air currents is gaged by means of improved Pitot tubes. Balloon models are produced electrolytically on wax models, thus allowing a remarkable accuracy and low weight to be obtained. A propeller testing plant has been added

A laboratory equipment likewise installed on plans by Prof. Prandtl, from funds of the First International Aeronautical Exposition (1909), held in Frankfort-on-Main, will most likely be used to supplement the Göttingen in-

(Concluded on page 300.)

The Most Powerful Government Wireless Plant

The United States Naval Station at Radio, Virginia

By John L. Hogan, Jr.

LESS than a year ago the Navy Department's most powerful wireless telegraph plant, at Radio, Va., near Washington, was completed, tested and taken over from the contractors. The towers and buildings were constructed for the Department from Navy plans, but the radio apparatus was designed and installed under the patents of Prof. R. A. Fessenden. The Radio station is the first of a proposed chain, linking by wireless the United States possessions throughout the Atlantic and Pacific, and its completion marked the first step in the realization of plans laid out by the federal radio authorities as early as 1909. At present work is going forward on similar high-powered Government plants in the Canal Zone and on the Pacific, so that before long it is expected that the more important centers of United States territory will be able to intercommunicate by naval radio, entirely independent of privately owned wire lines or cables.

Even in the absence of the additional power radio stations proposed, the plant near Washington is proving of great value. Time signals are sent out at several fixed hours each day, and by adjusting their wireless instruments to receive these impulses, officers aboard ships at sea are able to compare their chronometers with those at the Naval Observatory even though one or two thousand miles away. Equally valuable to the masters of vessels along the Atlantic seaboard are the

storm, ice, and derelict warnings transmitted at scheduled times along with various important weather and meteorological reports. Aside from these aids to navigation generally, the Navy Department is able to issue orders direct to any ship within two thousand miles or so, and likewise may transmit from the head offices of the wireless service, at Radio, direct to any of the naval installations along the Atlantic, and even to some of the Pacific coast stations. It has been the daily custom for the Radio station to exchange messages with the naval plants in range, beginning with Portland, Me., and taking in turn Boston, Newport, Brooklyn, Philadelphia, and the southern stations through North Carolina and Florida down to Colon, Panama. Tests between Radio and San Francisco are now being carried on, and it may soon be possible for these two stations to intercommunicate reliably at any time.

The apparatus and plant which makes possible this exceptional sort of radio transmission is interesting in all its details. As shown in Fig. 5, the station at Radio includes three enormous steel towers for supporting the antenna or aerial wires, and a large building divided into three parts. The central hall of this building contains the entire transmitting equipment, while the right hand wing (which is really an entirely separate structure) has in it the receiving room, a laboratory, and living quarters for the station personnel. The remaining wing is divided into additional laboratories, a machine shop and the executive offices of the Naval Radio Service. Near the extremes of the buildings, and 350 feet apart, are placed the two 450-foot towers. The 600-foot tower, shown in the foreground in the accompanying general view of the towers, is 400 feet from each of these, and stands at the acute apex of an isosceles triangle formed by the three. Fig. 4 shows a tower leg. Each of these legs rests on a similar reinforced concrete pedestal, and is equipped with a high potential switch for connecting the steel framework directly with wires buried underground. It has been found that the station transmits more efficiently when the towers are "grounded" in this way, and in addition the possibility of damage to the bases from lightning stroke is minimized.

From spreaders slung from the topmost point of each tower is threaded the enormous triangular fan of aerial wires which, when energized by the sending apparatus, sets up the powerful electromagnetic waves used in wireless transmission. These same wires are used in receiving messages, to collect from the ether the electrical power which brings signals from distant transmitters. On top of the wooden pole in the right-hand foreground of another illustration appears the aerial switch, which when operated by chains and levers from the receiving room connects the antenna wires to either the sending or the receiving instruments. A set of vertical wires drops from the big aerial fan to the top of the aerial switch, and by throwing the switch lever to the left or to the right the station is arranged either to send or to receive.

When the aerial switch is in its left-hand position the overhead air wires are joined to a large copper tube which is brought into the sending apparatus room through a glass window, as shown on the extreme right of Fig. 7. This photograph shows the entire transmitting equipment, and in it and Fig. 3 there may be traced the connection from the aerial through the tuning coils on top of the framework and down to the ground wires under the floor by way of a flat copper strip fastened to the central upright and leading through an electric current meter which shows just how powerfully the sender is operating at any time In the foreground of Fig. 3 is shown the 200 horse-power motor which drives the radio transmitter dynamos and rotary spark gap. The electrical power as furnished by the central station near Washington is not suitable for producing the clear ringing musical sparks used in modern wireless telegraphy, and so it is necessary to convert it by means of the motor and dynamos shown. After this conversion, the power is led through the sending-switch and transformer, and then, at a potential of about 25,000 volts, to the rotary spark gap of Fig. 6. In jumping from one of the stationary electrodes at the top of this gap to the revolving spokes and then back to the other stationary electrode the electrical condensers (the vertical cylindrical tanks of Fig. 2) are discharged through the left-hand coil shown at the top of Fig. 3. Sparks can occur only when the revolving spokes are directly under the stationary electrodes, and during the intervals between each two spark discharges the condensers are recharged with electricity from the transformer. The condensers themselves consist of steel disks interlaced and supported on rods inside of the tanks shown. These tanks are filled with dry air pumped up to a pressure of 200 pounds to the square inch, which high pressure prevents electrical leakage and consequent losses in the condenser. The compact installation of this powerful transmitter was made possible only by the use of these compressed air condensers.

There are 48 spokes on the rotary part of the spark gap, so that when this revolves at its normal speed of 1,250 revolutions per minute sparks will occur at the rate of 1,000 in each second so long as the sending-switch above mentioned is held closed. This sending switch is operated by a magnet and controlled from a Morse telegraph key placed in the operating and receiving room. When the operator presses this key for short and long intervals corresponding to the dots and dashes of the Morse telegraph code, the sparks pass for identical short and long intervals. The spark-discharge currents acting inductively across the transformer tuning coils shown in Figs. 7 and 3 force the aerial wire system to emit into space similar short and long groups of electromagnetic waves, which travel along the earth's surface to the receiving station. The fact that the sparks occur only one one thousandth of a second apart causes them to produce a high, clear, musical note, corresponding in pitch about to the second C above middle C on the piano, and this characteristic tone is reproduced at the receiving station. The receiving operator, holding to his ears a pair of ordinary Bell telephone receivers, hears the short and long musical sounds made by the transmitter, and is able to retranslate them into words according to the telegraphic alphabet, distinguishing them by their tone from the scratchy and meaningless sounds of natural atmospheric electrical discharges.

Fig. 8 shows the receiving- and operating-room of the Radio station. The wire from the aerial switch runs down the back wall and may be connected to either of the two complete receiving instruments which are installed. Underneath the operating table is the lever controlling the aerial switch on the pole outside, and mounted on the table top is the telegraph key by which Morse signals are sent out from the transmitter in the main building. Since messages must often be received from small stations at such great distances that the incoming signals are very faint, the receiving-room has been built as nearly sound-proof as possible. A system of mechanical and electrical interlocks protects the operator from electrical shock in case he should attempt to send before disconnecting the receiving apparatus from the aerial wires, and signal lights permit him to communicate with the engineers running the sending dynamos. A Telautograph, or writing telegraph, connects with an adjoining room in which are installed telephone and telegraph instruments connecting to the commercial lines, and by its use faint messages being received by radio may simultaneously be relayed out over the land wires by a second operator without danger of the clicking of telegraph sounders disturbing their reception.

In the months that the Radio station has been in operation it has not only filled a great need by the transmission of time and meteorological signals, but it has also demonstrated its service efficiency by the establishment of many new records for consistent long distance radio signaling. Its performance has indicated definitely that as the projected series of high powered stations reaches completion the United States will own a chain of wireless plants which will lead the world in efficiency and utility.

Attractions of Variable-star Observing

By Edward Gray, M.D.

IN all North America there must be some scores of telescopes possessed by amateurs which are more or less idle or at least producing no contributions to science, mainly because their owners do not know how to use them profitably. After a period of recreation among double stars, the moon and the planets, does not many an amateur weary of finding nothing new and possibly even relegate the telescope to the attic?

At this juncture comes in the value of variable stars. It can only be want of knowledge of the pleasure along with usefulness of variable-star observing which has kept back amateurs from pursuing this branch of study and recreation. Is there indeed any other line open to amateurs, if we except the observation and discovery of comets, wherein the amateur may do original work of value and where his results may be made useful to the present and to future generations?

It is the aim of this article to point out how inviting a field to amateurs is the observing of variable stars, mainly those of long period. To begin with, it is a field but little cultivated and where hundreds of thousands of observations are required by astronomers for study. One's equipment need not be expensive or elaborate. A good field-glass will suffice for a small minority of observations; but in general a refractor of some aperture between two and seven inches or a reflector of four to nine inches is requisite. Two observers are known to me who use rather small apertures, namely, two and two and a half inches; and each does good work.

An equatorial mounting is time-saving and convenient to work with, but cannot be reckoned essential; perhaps a majority of the observers now in this line use a tripod mount. This implies much more work at first in learning the fields, but rapid work thereafter. After two years' practice, for example, a valued correspondent cited an evening when he had made twenty-six estimates and was back in the house at 8.50.

The periods or cycles of the stars to be observed vary greatly in length, from two months to well nigh two years. Hence the state in which variables are found at any given time varies much; some are waxing in brightness, some waning: a few are at, or near, maximum, others at minimum, and still others resting before either rising or falling. All this insures variety, there is nothing tedious about observing variable stars. Surprises are frequent and one's interest is kept alive; for while some stars are perfectly regular and move like clockwork, others are irregular enough in their fluctuations to furnish all the mystery necessary Some are white, some yellow, some orange, some red, and a star red at or close to minimum may become orange or deep yellow near maximum It does not at all follow that because the last period of *SS* Cygni was nine weeks in length, the next one will be the same. On one occasion I found an interval of only forty days, an occurrence unique in my acquaintance with this star.

Beyond the telescope—and some place to use it—one's equipment requires only a good star-atlas and a number of charts of the variables to be studied The intending observer should associate himself with the Society for Practical Astronomy (Chicago) and its Variable-Star Section or with the Association of Variable-Star Observers (Norwich, Conn). The two bodies are co-ordinate, and most of those now engaged in this line belong to both. The necessary charts are procurable from the members and further from Harvard College Observatory, but conditional in this last case that a monthly report be made to its director. These charts once received, patience and perseverance do the rest. The way of the beginner is now easier than it was three or four years ago. There are magazine articles and manuscript "hints" which illuminate the path.

At present the literature is scattered in various magazines. The Society for Practical Astronomy publishes a *Monthly Register*, while the monthly reports of the Association of Variable-Star Observers appear in the magazine *Popular Astronomy* (Northfield, Minn.). These observations have grown to number 800 to 1,200 per month, according to the weather

More observers are needed, however, to carry on the work properly. Volume 55 of the Harvard *Annals* says, for instance, of X Monocerotis, "Very few visual observations have been published, since the star does not appear to go below the tenth magnitude. It could easily be followed with small telescopes; and continuous observations, when the star is not too near the sun, are needed to learn the nature of the changes of this interesting variable."

Seldom does one pursue this line of research for six or more months without describing it as fascinating. But if the mere observing is fascinating, what shall we say of the intellectual profit and expanse of mind to be attained therefrom? For there are problems connected with those stars which may exercise even the best intellects. Why do some variables like R Hydrae and ε Boötes shorten their periods, while others, like χ Cygni, lengthen theirs? Why does Mira Ceti sometimes barely exceed the fifth magnitude at maximum and at others attain the second? Why again does this star descend to the eighth magnitude only at some minima, but at others to the ninth, perhaps 9½? And why should it vary up to twenty days in either direction from its mean period of 331 1/3 days?

What physical cause is there why U Geminorum, *SS* Cygni and *SS* Aurigae should remain close to minimum for weeks or months and then suddenly rise, attaining maximum in a very few days? Why do very red stars usually have very long periods? And so on to more complex queries

Astronomers require a vast number of observations to accumulate data required for elucidating the many problems relating to variable stars

To sum up:

1 Observing variables is the chief line open to amateurs in which they may do good work and put their telescopes to useful account.

2. This pursuit has a charm which must be experienced to be appreciated It does not grow monotonous

3 It has an educative and intellectual value *sui generis*. This can be better understood after a practical acquaintance with the pursuit

4. It is not very costly.

5. It leads to the formation of desirable acquaintances; for a cordial *esprit de corps* exists among its devotees.

6. It requires method in observing and in recording results, and leads to habits of exactness; likewise to the setting of problems to be worked out and to a desire for higher knowledge. Its influence is altogether wholesome upon mind and brain and temper. It is an uplifting pursuit.

7. It is constructive, not destructive; and adds to the sum of human knowledge.

A Wonderful Model of a Copper Mine

By J. W. Grigg

PROBABLY the most elaborate and realistic copper mine model in any museum in the world has just been placed on exhibition at the American Museum of Natural History. It required more than three years' work to complete it. The mine reproduced is that of the Copper Queen Consolidated Mining Company's property at Bisbee, Arizona. It was executed under the direction of Dr. Edmund Otis Hovey, curator of geology, by Mr. Arthur Briesemeister and assistants, and was reproduced from accurate and first-hand study of the mine itself.

It is another of the many interesting exhibits planned and completed in recent years at the museum in an effort to bring the institution into closer touch with the people, and to make the institution as interesting as possible to the person without scientific training.

It was early in 1910 that Dr. James Douglas of the company informed the museum authorities that he was prepared to furnish the data and the means necessary for the construction of a large scale model of the mine. That summer Dr. Hovey took his assistants to Arizona, where the first thing done was to determine upon the point of view from which the picture of the model as a whole with its proposed painted background should be obtained. Practically the same view is now spread before the observer in the museum.

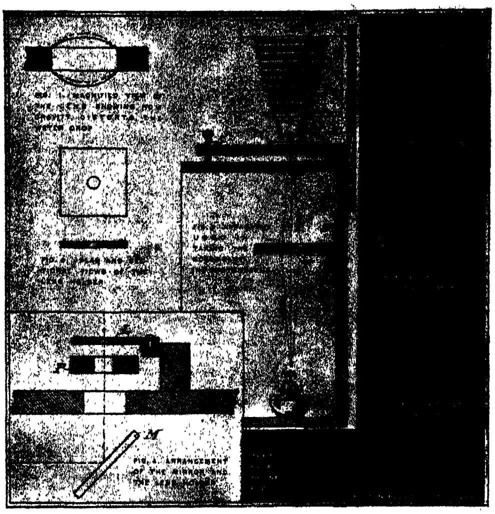
The model is 18 feet 6 inches long by 12 feet wide, representing an area 5,315 feet long by 3,418 feet wide. There are more than 500 structures represented in the model, including loading bins, dwelling houses and other buildings. After experimenting with wood, plaster, and other materials, the metal buildings, which are corrugated iron in the field, were made of brass covered with thin zinc foil scored to represent the corrugations to scale, while the dwelling houses and some small structures were made of cardboard. The head frames, loading bins, railroad tracks, etc., were made of brass.

The museum men in the field made records even of the color of paint on the different buildings, the nature of the material used in construction, the shape and character of the roofs, the position and nature of vines, shrubs, and trees, and in fact all other features that would be useful in making a naturalistic reproduction of the portion to be represented.

Originally it was intended to represent only the surface, with a painted background showing the Mule Mountains, but as soon as the work was actively begun it was considered of utmost importance that the underground workings should be represented as well. It was decided, too, to make a working model of a single stope on a scale of six feet to the inch to represent details that could not be indicated on the big model.

The representation of the underground work could be accomplished only by excavating the under portion of the model, and to place in the hollows thus formed reproductions of the stopes in solid wood, cut according to detailed plans of the levels as furnished by engineers of the company. Tunnels, raises, winzes, and shafts were likewise constructed to scale according to these plans and inserted in their proper places.

The sides of the model were used to give the geological sections along several vertical planes from 4,100 to 5,900 feet above the sea.



Water-drop microscope and photomicrographs made with it.

At work on the copper mine model of the American Museum of Natural History.

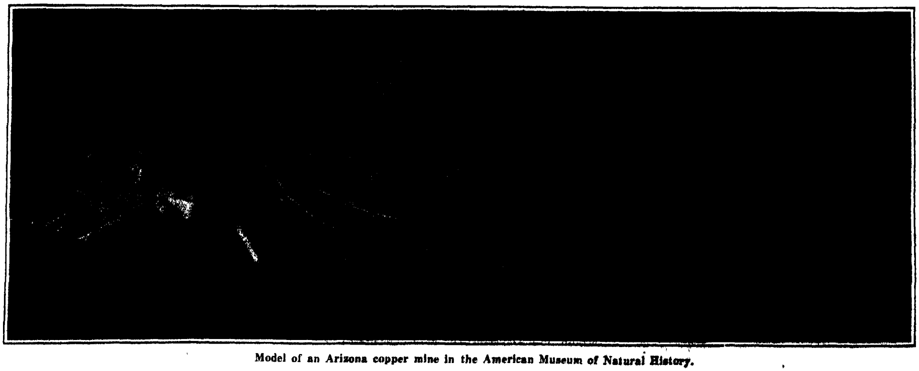
The Water-drop as a Microscope

By James Bailey

THAT a drop of water has the power of magnifying a hundred diameters astonishes most of us, and yet we are familiar with the properties of water, which make it suitable for a lens. We know that, when free, a drop of water assumes a spherical shape, we know that a lens is formed by grinding glass so that it has spherical surfaces, also that water like glass has the power of bending light rays. A free drop of water, therefore, has the two main properties of a lens, i. e., spherical surfaces and refraction. A free drop of water, however, is useless as a lens, but by a suitable holder the lens qualities of the liquid can be maintained and the drop readily handled.

The theory of the lens is quite simple. Consider the holder shown in Figs. 1 and 2, and neglect the effect of gravity for the present. The water or liquid used is prevented from falling out of the holder by adhesion. The surface tension of the liquid causes its surfaces to act like thin sheets of rubber fastened to the upper and lower edges of the holder. These edges being true circles, any pressure from within distorts them into spherical shells as shown by the dotted lines in Fig. 1. If the space between these is filled with water a lens is formed. The effect of gravity is to lower both surfaces and to distort them from the true spherical shape as shown by the solid lines. This corresponds to the actual condition and approximates the shape of the liquid lens as used. It can be easily shown that this distortion increases with the diameter of the holder, and as more liquid is added to

(Concluded on page 294.)



Model of an Arizona copper mine in the American Museum of Natural History.

The surface of the ground was modeled in clay on a wooden core. Many photographs had to be taken on the spot in Arizona so that every detail could be accurately reproduced.

Finishing the Work at Panama

WERE it not for the troublesome slides, the Panama Canal would to-day be a completed task; indeed, had it not been for the Cucuracha slide, the work of excavation would have been completed and the canal would have been made ready for opening at least one year before the time officially set for that event, namely, January 1st, 1915. In speaking of the Cucuracha slide, it must not be forgotten that this vast earth movement represents, after all, but a small part of the total amount of excavation that has been added to the original estimated amount by the earth and rock movements along the canal, and chiefly in the great Culebra cut.

To realize the magnitude of the task superadded by the slides, we must remember that it cannot be measured merely by the total yardage which has had to be removed. This in itself is large enough, Heaven knows, for it has reached the enormous total of 30,000,000 cubic yards, the removal of which in itself would constitute an engineering feat of the first magnitude. We must remember that in addition to the mere work of removal, the slides have imposed other burdens, due to their interference with the operation of the enormous excavating and removal plants, which have covered the bottom of the cut at all times during the progress of the work.

Frequently the slides have moved entirely across the cut, burying the tracks, filling up the drainage ditches, breaking the pipe lines for conveying air to the air drills, and otherwise upsetting the whole material organization.

Nevertheless, in spite of these interruptions and in spite of the enormous additional burdens of excavation imposed, it has to be recorded to the eternal credit of the engineers they have succeeded in steadily lowering the cost of excavation. This reduction in cost has been so great that it has about covered the increased cost of removing the slides.

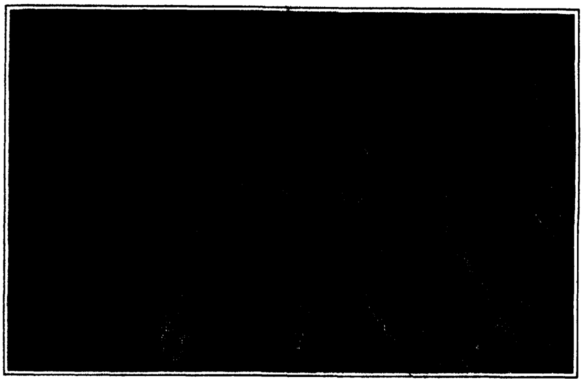
Completed locks at Panama, showing at left an electric towing locomotive.



Copyright 1914 by Underwood & Underwood

One of the Gatun locks serving as a drydock for submarines.

At the present writing a channel about 200 feet wide has been opened past the Cucuracha slide, and, as will be seen from our illustration, the dredges and the hydraulic monitors are steadily at work, the former removing the material from the toe of the slide, and the latter sluicing it away from the upper levels. According to the latest reports, Col. Goethals expects to have the channel so far cleared that it will be open for experimental navigation by ocean-going steamers on the first of July of the present year. The intervening time between that date and the day of official opening will be devoted to the drilling of the operating forces and getting everything into thorough working order; so that when the canal is opened to the commerce of the world, both the machinery and the operating forces may move with precision and a complete absence of delay.

The construction of the fortifications at each end of the canal is nearing completion and the mounting of the mortars and long-range rifles will probably be begun during the coming summer. Recently five submarines were dispatched to the Atlantic end of the canal to form part of the permanent defenses. Shortly after their arrival, the little craft were drydocked for overhauling and cleaning. Drydocks are being built at each end of the canal; but as these were not available, use was made of one of the locks at Gatun, and the submarines were docked side by side as shown in our illustration. So far as we know, this is the first time that locks have been used for this purpose.

A New Method of Sterilizing Milk

A NEW German invention for producing germ-free milk, known as the "biorisator," is said to be in successful use at dairies in Leipzig and Düsseldorf, and a favorable report upon it has just been made by W. Freund, who has investigated it on behalf of a German association of wholesale milk dealers

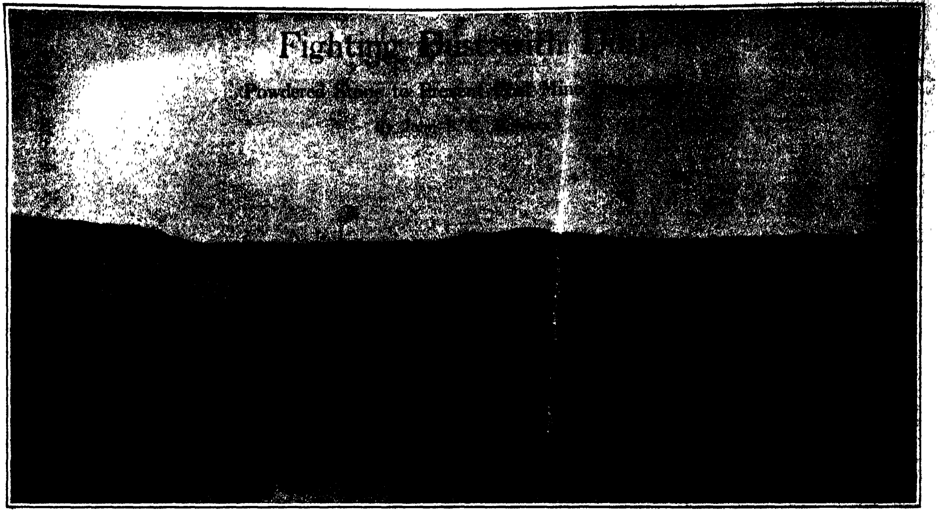
The advantage claimed for the biorisator process, as a substitute for the ordinary methods of pasteurization and sterilization, is that while it insures the destruction of pathogenic germs, it produces no change whatever in the chemical composition of the milk. The latter retains all the properties of raw milk, and can be used for cheese making, besides keeping much longer than either raw or pasteurized milk.

The essential features of the process are that the milk is poured into a pressure chamber, where it is subjected by a pump to a pressure of 4 atmospheres; it is then conveyed by the same pressure to a large cylindrical vessel, which it enters in the form of a fine spray, and is, at the same time, subjected to a temperature of 167 deg Fahr From the cylinder it passes through a cooler, where its temperature is rapidly lowered to at least 50 degrees From this it flows to a bottle-filling machine The peculiar merit of this process appears to be that the milk is subjected for only a brief time to the sterilizing temperature while in the form of a spray Another advantage is that no milk is lost by evaporation.

Fighting Dust with Dust

Powdered Stone to Prevent Coal Mine [illegible]

By [illegible]



General view of the Experimental Explosion Station, showing the 7½-foot gallery.

THE SCIENTIFIC AMERICAN SUPPLEMENT of August 23rd last, contained the reprint of a paper upon the "Effects of Incombustible Dusts on the Explosion of Gases," read by Prof. Harold B. Dixon, F.R.S., and Colin Campbell, M.Sc., before the Manchester (Eng.) section of the Society of Chemical Industry. The investigations described in this paper had their origin in the proposal to use stone or slate dust in coal mines, in order to minimize or prevent the dangerous explosions of coal dust, which have been proved to add greatly to the devastating effects of fire-damp explosions in dry and dusty mines. The objection had been raised (based on some experiments carried out by Sir Frederick Abel in 1881-1882) that incombustible dust such as stone or slate dust would *add to*, rather than *minimize* the dangers of explosion in mines, because catalytic action would come into play, and would accelerate the rate of the chemical combustion of the carbon-monoxide or methane with the oxygen of the air.

The investigations referred to by Dixon and Campbell proved *conclusively that* Sir Frederick Abel had drawn wrong conclusions from the results of his experiments in 1881-1882, and that *the presence* of incombustible dust in a mine, so far from accelerating the rate of combustion, exerted a cooling and quenching effect on the flame. The use of such dusts in coal mines cannot therefore add to the danger or intensity of fire damp explosions.

Since Dixon and Campbell's paper was published, the fifth report of the Explosions in Mines Committee has been published,[1] and as this contains very important recommendations and proposals regarding the use of stone dust in mines, certain of the "*conclusions*" arrived at by the committee are given below

"A slowly traveling inflammation, such as is produced when a ready made dust cloud is ignited by a large jet of gas (unaccompanied by concussion) is at first capable of licking up coal dust deposited upon the *surface of an* incombustible dust and propagating itself for some distance until sufficient violence is developed to raise the incombustible dust also, and this raising of the incombustible dust is more readily effected when a lighter or more buoyant dust, such as flue dust or fuller's earth, is employed, both coal and incombustible dust being raised in suspension together, and the flame soon dying down"

. . . .

"Incombustible dust is more effective in preventing the ignition of coal dust than in checking an inflammation that has started. It should, therefore, be distributed uniformly throughout those galleries of the mine subject to the danger of coal dust ignition, and if maintained in the proportion of between one and two parts by weight of incombustible dust to one of coal dust, the chances of such ignition taking place would be very small. Even a small proportion of incombustible dust (20 or 30 per cent by weight) has a marked effect in checking an incipient inflammation.

"The disposal of incombustible dust in zones, or in easily disturbed masses concentrated in certain positions, *leaving portions of the roads untreated, is, we think, not likely to be effective.*

"In the case of mild inflammation, an incombustible dust that is readily raised and floats in the air, has been found to be more effective than one which, owing to its shape or density, is less buoyant.

"Shale dusts, or even heavier dusts, such as sand, are, however, effective, when sufficient violence has been attained to raise them in suspension in the air."

Having thus formulated the conclusions, which appear to follow from their experiments at Eskmeals and elsewhere, the committee make some practical suggestions, and here again it will be best to quote their report:

"It must be distinctly understood that our experiments have traversed, as yet, only a portion of the subject, and that what we propose is advanced as a provisional precaution which may be found on further experience to need extension. But since these experiments have clearly shown the great difficulty of initiating an explosion in a gallery where the coal dust has been mixed with an easily raised incombustible dust, so that the mixture contained at least 50 per cent of incombustible material, we are confident that the dust in a mine so treated would be relatively safe from ordinary ignitions, and consequently that the chance of a *disastrous explosion would be greatly diminished.*"

. . . .

Since this admixture with 50 per cent of incombustible matter, which can be carried out in a simple and practical way, confers on coal dust such power of resisting inflammation, it might be, in our opinion, most *usefully adopted now, even if further experiments may lead to extensions, or other methods be found more efficient.*

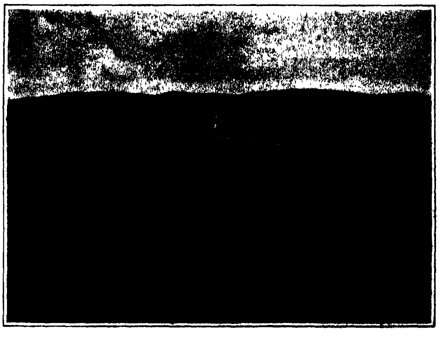
We think therefore that, as an alternative to watering, the treatment of coal dust by an incombustible dust—so as to maintain an excess of incombustible matter in the mixed dust—might be adopted as fulfilling the requirements of the English Coal Mines Act of 1911.

By Section 62 (3) and (4) of that Act it is enacted that:

"The floor, roof and sides of the roads shall be systematically cleared so as to prevent, as far as practicable, coal dust accumulating; and . . . systematic steps, either by way of watering or *otherwise* . . . shall be taken to prevent explosions of coal dust occurring or being carried along the roads. Such a systematic step

(*Concluded on page 294.*)

Free end of the gallery during a test.



Junction of the 7½-foot gallery with one 3 feet 2 inches in diameter.

---

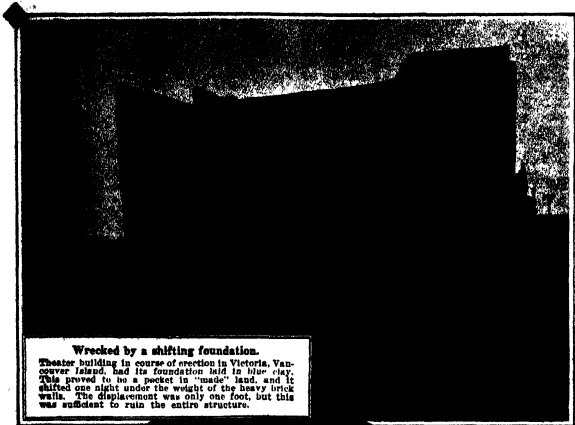
Curiosities of Science and Invention

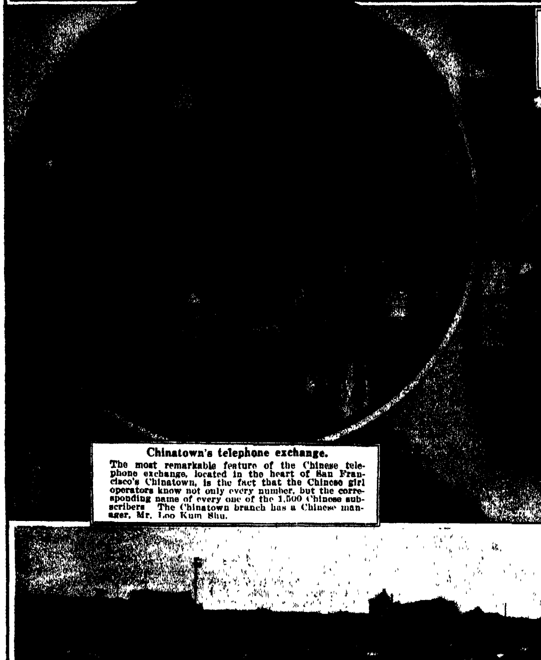


Wrecked by a shifting foundation.

Theater building in course of erection in Victoria, Vancouver Island, had its foundation laid in blue clay. This proved to be a pocket in "made" land, and it shifted one night under the weight of the heavy brick walls. The displacement was only one foot, but this was sufficient to ruin the entire structure.

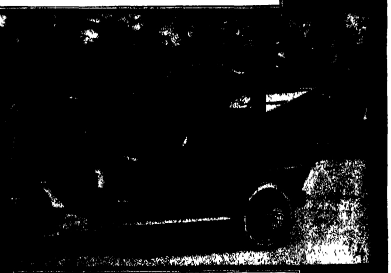
Motorcycle chemical fire-engine.

There has recently been developed in Oklahoma City a novel emergency fire-engine, consisting of a regular motorcycle equipped with two chemical tanks on either side of the rear wheel directly back of the driver's seat. This equipment can be brought into action more quickly than an automobile fire-engine.



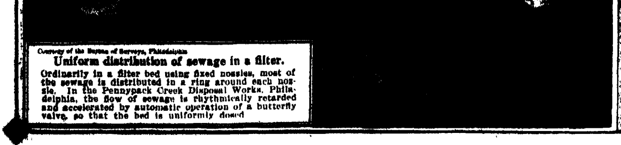
Chinatown's telephone exchange.

The most remarkable feature of the Chinese telephone exchange, located in the heart of San Francisco's Chinatown, is the fact that the Chinese girl operators know not only every number, but the corresponding name of every one of the 1,500 Chinese subscribers. The Chinatown branch has a Chinese manager, Mr. Loo Kum Shu.



Front drive tricycle motor car.

The idea of using a front drive in motor cars dates back to the very earliest days of the automobile, when efforts were made to use the motor in front of the vehicle as a substitute for a horse. Now, apparently the idea is being revived, as may be noted in the recent photograph.



Courtesy of the Bureau of Surveys, Philadelphia

Uniform distribution of sewage in a filter.

Ordinarily in a filter bed using fixed nozzles, most of the sewage is distributed in a ring around each nozzle. In the Pennypack Creek Disposal Works, Philadelphia, the flow of sewage is rhythmically retarded and accelerated by automatic operation of a butterfly valve, so that the bed is uniformly dosed.

Slot machine for the job seeker.

A Los Angeles inventor has installed a "job seeker's" slot machine on the streets. The glass case shows cards stating conditions offered by employers. Dropping a quarter in a slot releases the corresponding card, which bears the employer's address on the back. If he finds the job taken, the quarter is refunded by the firm operating the machine.

ODDS AND ENDS FROM THE EDITOR'S DRAWER.

RECENTLY PATENTED INVENTIONS

These columns are open to all patentees The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN

Pertaining to Apparel.

WAISTBAND LINING FOR TROUSERS.—A A BROWN, care of A. L Palmer Co., 818 Lafayette St N Y, N Y By means of this invention linings of trousers are sewed entirely by machine thus doing away with the necessity of placing the work outside the factory, in homes as is the custom. These advantages accrue from a novel construction of waistband lining which can be quickly made and attached to the garment, and at the same time present a neater appearance than do waistbands sewed to trousers by hand.

TAILOR'S RULE —M. CARROLL, 196 Madison St, New York, N Y This invention relates particularly to rules for tailors' use and for ruling off garments or patterns, and it provides a structure in which the various measurements have been arranged in systematic order so that a proper pattern may be cut with a minimum amount of measuring

ARCH SUPPORT FOR SHOES.—P. IACOVINO, 199 Prince St., New York, N. Y. An object here is to provide a support which may be applied to any footwear and at any time. The support is provided with suitable bracing members for supporting the arch of the foot, the entire structure being also formed so as to be readily inserted in a shoe after its completion

Electrical Devices.

ELECTRICAL FURNACE —C. C. WHITMORE, 104 E First St, Butte, Mont. The advantages in this case are The utilization of the current in two ways, to wit, in heating electrodes and in heating ores and substances intermixed therewith by conductivity thereof To prevent overheating of electrodes To control distribution of ores or other materials upon which the furnace operates, a greater amount of material being passed into the furnace at points where the heat thereof is comparatively great. To enable a group of electrodes to be readily removed relatively to another group thereof for purposes of distributing the current

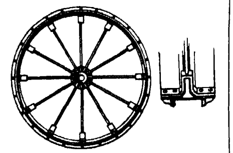
SIGNALING DEVICE FOR PARTY LINE TELEPHONES.—T. KERNAN, 428 Fifth Ave., N E. East St. Cloud, Minn The improvements in this case indicate to a user of the telephone whether a person other than the party with whom he desires to talk has taken down or put up his receiver, and also indicates the identity of the party who is listening in. It may readily be attached to instruments of the ordinary type without interfering with the circuit

Of Interest to Farmers.

AUTOMATIC HOE —A THOMPSON, 122 Jefferson St., Spartanburg, S C. This invention relates to agricultural machinery, the more particular purpose being to produce a hoe having a number of advantages and adapted for use in a variety of different relations, being of special service in connection with the cultivation of cotton

BEET BLOCKER —H. W GRIBLER and A. G. GRIBLER, 741 Prospect Ave, Van Wert, Ohio. The purpose here is to provide a beet cultivator especially adapted for cultivating beets in the field in the opposite direction from the direction of the beets in the row, and wherein mechanism is provided for protecting the plants during the cultivating operation

TRACTION WHEEL FOR PLANTERS.—E. J OGDEN, Springfield, Ill This application is a division of the application Serial No 664,000, filed Dec 5th, 1911, patented Nov. 25th, 1913, No. 1,079,797, and the invention relates to traction wheels for corn and other planters



TRACTION WHEEL FOR PLANTERS

The object of the present invention is to provide a wheel with means which will straddle the hills of corn or other seed, or which can be made a traction wheel by closing the space between the ribs as shown in the smaller engraving A further object is to provide a wheel with means which will effectually prevent it from slipping

STRAW STACKER —J MASERANG, 6653 Manchester Ave., St Louis, Mo The object here is to provide a stacker of the blower type, wherein mechanism is provided in connection with the stacker for permitting straw as it issues from the stacker to be directed to any parts of the stack, the said means being operated from the threshing machine

ELEVATOR.—E. H. ZIMMERMAN, P. O Box 67, Perry, Ill. The purpose here is to provide an elevator which may be transported from place to place and may be operated from any suitable source of power, and which is especially adapted for handling grain, such as corn and wheat, vegetables, such as potatoes or any other article that can be handled with a scoop shovel.

EVENER.—R. H. KEITH and F. H. BROOKS, Rowan, Iowa. Address the former. The patent provides a device especially adapted for use with farming implements of the drag class, especially of the folding type, and so arranged that the evener may be folded with the drag, in passing through gates or narrow passages.

Of General Interest.

SHAVING BRUSH.—H. ROBINSON, 1 First Ave., Winfield, N Y The principal object here is to provide a collapsible handle having a tubular portion to form a pocket for the brush tuft, and to construct the handle or mounting to form a box like casing, the ends whereof are closed to prevent the admission of dust to the tuft and to prevent the tuft moistening surrounding surfaces.

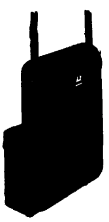
HOLE CLOSURE.—D. J. DIEL, 3614 Rockaway Road, Woodhaven, L I., N. Y Among the objects particularly aimed at is to provide a cheap reliable metal closure which may be quickly secured in place, substantially closing the hole or opening, but which may be removed with facility by a suitable simple tool, when necessary, for reopening the hole

ANVIL ATTACHMENT.—J R STULL, 1121 South Los Angeles St, Los Angeles, Cal This invention provides an attachment for an anvil having an arm, which extends through an opening in the top of the anvil, the arm being provided with a head, which projects longitudinally of the anvil at opposite sides of the arm, the last being pivoted to a lever, fulcrumed to the anvil block, so that this lever may be operated by the foot of the smith, to conveniently clamp the member between head and anvil

OPTICAL INSTRUMENT — W WORK, care of H. S. Hewett, 119 Main St., Brockton, Mass. The inventor provides an instrument to be used in conjunction with a plano retinoscope, and arranged to permit of quickly and accurately determining the amount of refraction of the eye of a patient under observation by an oculist or other examiner, to insure fitting the patient with eyeglasses or spectacles having correct spherical, cylindrical or compound lenses.

ELEVATED CARRIER —F. L PUTNAM, Lihue, Hawaii This invention pertains to elevated carriers and has particular reference to apparatus adapted for various uses such, for instance, as gathering various commodities over a field or wide scope of operation, and conveying the same to a distant point for delivery or deposit

COMBINED CAMERA CASING AND FILM CARRIER —R R LIVINGSTON, Clermont, N Y. This invention relates to photographic cameras using roll films, and its aim is to provide a combined camera casing and film carrier arranged to permit carrying extra films without increasing the size of the camera casing, and to allow convenient removal of a roll film from the film carrier whenever it is desired to use such film in the camera or for storing the exposed roll film in the carrier.



COMBINED CAMERA CASING AND FILM CARRIER.

AUTOMATIC CLOSURE DEVICE FOR LUBRICATORS —F BLED, Versailles, Seine et Oise, France The characteristic qualities of the apparatus consist in the features that the operations of opening and closing are very rapid, that it completely uncovers the lubricating orifice, that it is absolutely tight, and that by reason of its method of fitting it prevents the entrance of dust when it is open and that, moreover, no throwing-out of oil takes place when it is closed.

PROCESS FOR MAKING PHOTO STEREOTYPES FOR TYPOGRAPHIC PRINTING PRESSES —C BAECHLER, Lompoc, Cal. In this instance the invention has reference to the process of making printing blocks directly from any negative or film, by employing bichromated gelatin or glue, and a screen or chemical grain to form the printing block.

OPERATING TABLE FOR USE IN ANIMAL RESEARCH —KATHARINE STEBBINS, 437 W 59th St, Manhattan, N. Y, N Y The table is constructed with posts having hooks at their upper terminals, which engage eyes of adjustable leaves which rest on cross-bars supported on screws which mesh in threaded openings in the table, so that by turning the screws the cross-bars may be raised or lowered, carrying with them the leaves. The sides of the leaves are curved over the lugs, which permits the movement of the leaves without interference by the hooks on the posts.

WIRE FENCE STRETCHER.—T. R. G. SMITH, Warren, Ark. In this invention use is made of a jack screw operated by a T-handle similar to the handle of the common bench vise, and an elongated tubular base that is threaded internally to secure the jack screw, and bears against the post to which the fence wires are to be secured. The wires are received in and gripped by a standard, which is connected with the jack screw through the medium of a yoke that is adjustable to different heights on the standard, and is swiveled to the jack screw.

COLLAPSIBLE TRUNK.—B. L. URDANG, 11a W 118th St, New York, N Y. Among the special objects of the invention is to produce a trunk so as to be strong, rigid and durable in use for shipping or storing purposes and adapted to be collapsed when empty and with all of the parts substantially inclosed between the bottom and the lid.

BURGLAR ALARM.—J. HOFMANN, 157 E. 55th St., Manhattan, N. Y., N. Y. Use is made of a barrel having a closed upper end forming an anvil against which a detonating cap is to be exploded, the barrel being adapted to be suspended from one end of a cord having its other end clamped in place by the movable object at the time the latter is shut, so that on opening this object the cord is released to allow the barrel to drop. Use is also made of a screw cap and a firing pin slidable in the barrel and screw cap and projecting below the screw cap, the pin being adapted to carry a detonating cap to be exploded against the upper end of the barrel at the time the barrel drops and the pin strikes the floor.

BURGLAR ALARM.

HORSESHOE.—G STAPLES, Oshkosh, Wis The present invention relates to horseshoes and is an improvement in that class of horseshoes provided with a resilient cushion or pad and with removable calks, the object being to provide certain novel details in the construction and arrangement of the several parts.

REFRIGERATING APPARATUS.—W. A. OWEN, Johnson City, Tenn. In carrying out the present invention, it is the inventor's purpose to provide a refrigerating apparatus whereby articles or eatables such as meats and the like of a perishable nature, may be kept cool and by means of which the operation of making ice may be carried on.

SUPPORT —W A POWEL, 108 E Main Cross, Taylorville, Ill The support is designed for holding the pipe sections of the water main in position in the trench for conveniently joining adjacent sections, and for pouring the lead into the bell or spigot joints a distance above the bottom of the trench to avoid cutting bell holes for leading and calking purposes, the support being arranged to permit of gradually lowering the united pipe sections to their final resting place in the bottom of the trench.

HORSESHOE CALK —F F. HEISELMANN, Cox Place and Edwards Rd., Hyde Park, Ohio This invention refers more particularly to the combination with a horseshoe provided with a recess, of a calk having a point and a head adapted to be received in and fit into the recess, and a keeper co-operating with the calk and recess of the horseshoe to secure the calk against accidental displacement

BASKET.—M. J WHEELER and F. B FOSTER, Peterboro, Hillsboro Co., N. H. This improvement relates more particularly to a fruit or vegetable basket, and it is a design of the invention to provide a basket by which the fruit or vegetables may be handled and dumped from the basket without injury and with convenience.

POST OR POLE —J M. BOOTH, care of Evans State Bank, American Falls, Idaho. The object in this instance is to provide a metallic post which may be quickly and economically formed, which will effectually receive and hold longitudinal fence wires and thus be adapted for use as a fence post, and which may be driven into the earth and rigidly maintain itself in position

SHAVING CREAM.—P C MAGDLEN, 63 W. 107th St., New York, N. Y. The object in view is to provide a composition adapted to be used on the face in place of an ordinary shaving soap, which will soften the beard and allow the razor to be used in the usual manner while combining with such characteristics the usual characteristics of a good quality of face cream.

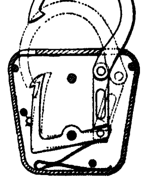
METHOD FOR LOCATING THE PLACE AND CHARACTER OF A LIQUID COMING FROM STRATA IN A WELL.—T. A. BEECHER, Box 352 Drumright, Okla. The object here is to determine and locate strata containing liquids when drilling a well or in a drilled well. The inventor employs proper coloring matter, placed in a predetermined position in the well, and then the liquid from the well is gradually discharged and analysed to ascertain if the so discharged liquid contains the coloring matter. Mr. Beecher has invented another method in which he employs proper coloring matter diffused in a predetermined place in the well, then displacing the colored liquid from the well, and then getting samples of liquid from different depths in the well and ascertaining if the samples contain any of the coloring matter diffused.

PROCESS OF MANUFACTURING COMPOSITIONS OF MATTER.—L. LILIENFELD, Zeltgasse 1, Vienna, VIII, Austria-Hungary. This invention relates to improvements in the process of manufacturing compositions of matter by means of heating a drying oleaginous substance with an aromatic substance in the presence of a condensing agent, as described in the applicant's prior patent, No. 1,037,158.

LETTER BINDER.—C. E. O'NEILL, care of First National Bank, Butte, Mont. An object here is to provide a binder of any suitable size which is adapted to embrace all of the sides and ends of the package, and which automatically accommodates itself to the size of the package, making it easy for the binder to be manipulated for the purpose of receiving or delivering letters on other parts to or from the package.

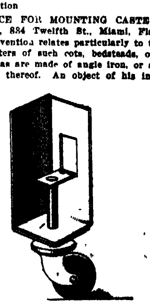
Hardware and Tools.

PADLOCK.—J. SUKUP, 603 Munkivitz Ave., Cudahy, Wis. The padlock represented in the engraving is one difficult of manipulation for opening, except by one familiar with its construction and operation The padlock may be unlocked by manipulating the shackle from the outside, but may not be unlocked by a key or other instrument, the lock, however, being provided with a key hole so as to present the appearance of an ordinary padlock and thus mislead unauthorized persons attempting to pick the lock, into believing it to be one of usual construction



PADLOCK.

DEVICE FOR MOUNTING CASTERS.—C. J. BELL, 884 Twelfth St., Miami, Fla. Mr. Bell's invention relates particularly to the legs and casters of such cots, bedsteads, or other articles as are made of angle iron, or at least the legs thereof. An object of his invention is to provide caster bearings formed integrally with the sides of the angle iron legs, thereby to provide a simple and strong construction. The engraving gives a perspective view, showing the lower portion of an angle iron leg embodying the improvement



DEVICE FOR MOUNTING CASTERS.

WRENCH.—W. CARMAN, 6 Liberty St., Ellenville, N. Y. This invention has reference to a wrench of the quick-acting type, wherein a movable jaw is locked with respect to the shank or handle bar by a pawl or toothed lever which is held in engagement with the teeth on the [illegible] during use of the wrench.

MORTISE LATCH AND LOCK.—A. C. [illegible], 277 Rider St., Bronx, N. Y. In the present invention the object is the provision of a new and improved mortise latch and lock, more especially designed for use on fireproof swing doors and hollow metal casings, and arranged to provide multiple locking contents in a simple and effective manner.

SAW SET AND JOINTER.—A. DUDGSON, 617 Spring St., Latrobe, Pa. This inventor provides a saw set and jointer which will set a number of teeth at a time, in which the tooth bit can be set at different sizes of saw teeth, and in which the motion of the setting tool is adjustable and which, also, is adapted to receive a file for jointing the saw.

PENCIL SHARPENER.—O. W. NIEDOMANSKI, 721 Rock Creek Road, Washington, D. C. This improvement has reference to pencil sharpeners of the type suitable to be carried in the pocket and easily handled, the more particular purpose being to increase the efficiency of the sharpener while promoting the simplicity of the construction thereof.

Heating and Lighting.

MECHANICAL MATCH LIGHTER.—E. D. FITZPATRICK, 408 Paxton Block, Omaha, Neb. The inventor provides a time-released mechanism to ignite a match by abrading the head thereof; provides an alarm clock with means for lighting a match by abrasively engaging the head thereof; and provides a clock mechanism with means for holding a match in operative position, and with means for igniting the same by abrading the head thereof when released by the clock mechanism.

FUEL APPARATUS.—J HYDE, deceased, care of Catherine Hyde, administratrix, 315 Summit Ave., Mt. Olive Station, Pitt, Pa. This invention relates to apparatus for adapting coal and other like fuel for efficient combustion in a finely divided state, admixed with air, and it refers more particularly to apparatus of the class described, which comprises a casing having a fuel inlet and an outlet, a rotary comminuting device in the casing, and a blower for drawing air in the casing, and forcing the fuel mixture through the outlet.

Household Utilities.

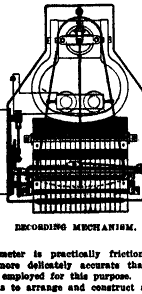
BED COOLER OR HEATER.—G. F. SHEPPARD, Box 51, Dodge City, Kan. This device is formed of a pair of similar receptacles having ordinarily the length of an average human body, which can be positioned longitudinally, or otherwise, in a bed, each of said receptacles having means whereby it can be made a cooler or a heater.

Machines and Mechanical Devices.

VIEW CHANGING DEVICE.—W C. UPP, 30 Church St., New York, N. Y. This invention has reference to view changing devices and has particular reference to means for exhibiting cards, pictures or the like, in such manner as to provide an automatic change from one view to another at regular intervals

THREAD CUTTING ATTACHMENT FOR SEWING MACHINES.—R. L. COLEY, Kannapolis, N. C. Address J. W. Cannon, Concord, N. C. The purpose here is to provide a mechanism adapted for connection with certain types of sewing machines, for automatically clipping the thread between succeeding pieces of work, as each piece is completed, and wherein means is provided for retaining the operation of the cutter during the passage of the work beneath the needle.

RECORDING MECHANISM—H W. PAYNE, 65 Hobart St., Rochester, N Y This invention relates to recording mechanism designed especially for recording delicate and accurate measurements or quantities such as volts An object is to improve this class of devices whereby the operation thereof with respect to the galvanometer is practically frictionless, and hence more delicately accurate than devices usually employed for this purpose. A further object is to arrange and construct an instrument which is adapted for making variable records upon a chart having rectangular coordinates whereby such records are more easily and reliably read than when made on other forms of charts.



RECORDING MECHANISM.

FRICTION CLUTCH.—N. J. WIGGINTON, Winchester, Va. This improvement provides a friction clutch which will transmit to a machine a given amount of power, and which, when the load on the machine increases beyond a certain point will turn idly, thereby obviating any danger of injury to the machine, such as might occur if the clutch were not used.

ELEVATOR INDICATOR.—F. A. BORDTCHER, Bergenfield, N. J. This invention is adapted to automatically operate for indicating not only the floor at which the elevator may be positioned and the progress of the elevator from one floor to the other, but to indicate the direction of travel of the elevator regardless of whether or not the same is moving or stationary, so that a person looking at the indicator may observe whether the particular elevator is making an up or down trip.

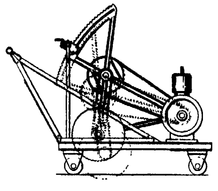
RESUSCITATING APPARATUS.—C. M. HAMMOND, Memphis, Tenn. This inventor provides a casing which may be placed over the body of a patient, and through which the arms, neck and legs may project. This casing forms an air space which may be relieved of the external air pressure, thereby causing the air within the lungs to expand and a rush of air through the air passages into the lungs, similar to the movement of air caused in natural breathing.

ADJUSTABLE CRUSHER HEAD.—E. L. PEMBERTON, 15 Livingston St., New Haven, Conn This invention relates to crusher heads which may be used for rock and other similar crushers, and which are customarily mounted on a main shaft. These heads are usually manufactured from cast manganese steel to provide the necessary hardness, but as crusher heads when made of this material work loose on the shaft, the present improvement provides means for adjusting and tightening the crusher head on the shaft from time to time.

PUMP CYLINDER.—L. G. EDDY, Huntington, N. Y. In this case use is made of a sleeve extending into the lower end of the pump cylinder and provided at its lower end with a screw thread, a screw, a coupling removably connected with the sleeve, and a packing on the sleeve intermediate the said pump cylinder and the said coupling.

MEASURING MACHINE.—A. F NIMS Philadelphia, N Y The purpose of the invention is to provide a machine by means of which the respective positions of the mixtures can be easily regulated, and in which obstructions or bodies too large to pass through a hopper are automatically removed without injury to the machine.

MACHINE FOR CUTTING PAVING.—G. PERKINS, 511 E St., N W., Washington, D C. This invention relates to a machine for cutting asphalt and other paving through the use of a power-driven circular saw, the object being to provide a machine including means by which to support a circular saw in such manner that it may be adjusted toward and away from the ground and held in selected position for cutting the paving or other material to a desired depth



MACHINE FOR CUTTING PAVING.

ILLUMINATED CLOCK—A MORINA, 122 Stone St., Newark, N J. To illuminate a clock, this inventor arranges a holding means for a small lamp, and a chamber between the clock works and the dial. A side door affords access to the lamp chamber. An extinguishing device is actuated at a predetermined hour by an adjustable trip, turning with the hour hand arbor.

LOOM FOR WEAVING ORIENTAL KNOT PILE FABRICS—J. K DALKRANIAN, care of M. N. Costikyan, 200 Fifth Ave., Manhattan, N. Y., N. Y This invention relates to pile fabric looms such as shown and described in the application for Letters Patent of the U. S., No. 265,886, filed by Mr. Dalkranian on June 19th, 1905. The object is to provide a pile fabric loom more especially designed for weaving pile fabrics of the oriental rug type, and preferably such having Persian knots and a reinforced body, as shown and described in the application for Letters Patent of the U. S., No. 312,143, filed by this inventor April 17th, 1906.

POPCORN VENDING MACHINE.—G. A. LIGHTNER, Olustee, Okla This invention relates more particularly to a vending machine in which fresh corn is fed to the heated popping drum, popped for a predetermined time, salted, and delivered to the purchaser in a definite sequence of operation, all of the mechanisms being actuated by a coin-controlled device.

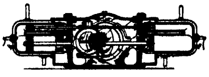
ATTACHMENT FOR ALARM CLOCKS.—E. H. PRATT, Lompoc, Cal. The object of this invention is to provide such releasing means as may be wholly mounted on the exterior surface of the clock without necessitating ingress or connection within the same, which is brought into operation by a friction clutch member disposed upon an exterior portion of the alarm winding arbor and adapted to engage the same when it is turned in one direction only.

HUB-FACING ATTACHMENT FOR CAR WHEEL BORING MILLS.—F. V. MCDONNELL, care of M. P. Lines, W. of Pittsburg, Logansport, Ind. The general object of the invention is to provide an attachment whereby the feed screw for the facing cutter can be power-driven so as to relieve the operator of the work of turning the screw, it being merely necessary for the operator to initially adjust the facing cutter and then interrupt the feed of the latter when the cut has been completed.

Prime Movers and Their Accessories.

ENGINE—J. H. RICHARDSON, Verdon, Neb. The purpose here is to provide an engine for utilizing the expansive force of fluids, wherein a series of pistons is provided, the central piston moving between the lateral pistons and in opposite direction to the said pistons, and cooperating in alternation with the said pistons as an abutment against which the motive fluid may react.

INTERNAL COMBUSTION ENGINE.—J W. PITTS, Hotel Stratford, Houston, Tex. This invention provides novel means for ridding the cylinders of the spent gases or products of combustion and for cooling the cylinders It provides means for doing away with the back pressure on the exhaust, and this is accomplished by means of a device which makes use of the momentum acquired by the gases themselves. It provides a device whereby a plurality of pistons may be connected to work absolutely in unison, and provides a novel form of compression chamber for the explosive charges



INTERNAL COMBUSTION ENGINE.

STARTING DEVICE FOR INTERNAL COMBUSTION ENGINES.—D. E CROUSE, 3 North St., Annapolis, Md. An object of the present invention is to provide a device which may be started from any point by the mere compressing of an electric push button, the subsequent operation of the device serving to start the internal combustion engine and to restore the starting mechanism to its normal position

Railways and Their Accessories.

BOILER WASHING SYSTEM.—W. M. SAXTON, Spokane, Wash, and C C HODGE, Winnipeg, Manitoba, Canada Address the former, 46 Canada Life Building, Spokane, Wash This invention provides means whereby the boilers of a plurality of locomotives, each under a different steam pressure, may be blown off simultaneously without one interfering with the other, and any member may be washed out at the same time.

SWITCH STAND LOCK—C WOOD, P O Box 331, Moulton, Iowa. This device is capable of being applied to existing stands without radical change, by means of which the dropping of the lever into inoperative position after setting the switch to either position will positively lock the switch, that is, will lock the operating lever to the stand Mr Wood has invented another switch stand lock which provides means in connection with a switch stand for locking the operating lever to the stand, with the switch in open or closed position, wherein the locking means is actuated by the dropping of the operating lever into inactive position

SAFETY SWITCH POINT—J B COBB, JR., 611 N Chapman St, Shawnee, Okla This invention is an improvement in safety switch points, and has for its object the provision of a switch point of the character specified, wherein the points will be at all times held in normal position regardless of defects in the switch, stand, or the connecting rod

Pertaining to Recreation.

TOY—E LOGAN, 1900 Kater St, Philadelphia, Pa. This toy is adapted to be trundled along the floor by a child, whereby it is adapted to give a succession of rings on a bell attached thereto. An object is to provide a device in which a bell may be sounded by movement of the same in one direction, and whereby said bell will remain silent by movement in the opposite direction.

CAROUSEL.—S W BRUNDAGE, care of Charles W. Parker of Leavenworth, Kan This invention provides useful improvements in merry-go-rounds or carousels whereby a pitching and rolling movement is given to a boat or similar vessel while being bodily carried around, so as to enable the occupant of the boat to enjoy a ride similar to that when aboard a pitching or rolling marine vessel on troubled or disturbed waters.

ANIMATED TOY.—A. GUND, 220 W 19th St., Manhattan, N. Y., N. Y. This invention provides a toy in doll form or simulating an animal, and is arranged when alternately pressed and released to actuate certain members of the body, such as arms, legs, wings, or the like, and at the same time cause the production of sounds similar to those emitted by the simulated child or animal.

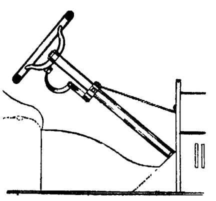
Pertaining to Vehicles.

LOCK FOR AUTOMOBILES—J. A. CAMPBELL, Carbondale, Ill The object here is to provide an automobile with a lock, the lock having a bar with a lug which may be moved into engagement with a lug on a foot pedal arm for operating the clutch, so that when the bar is secured with its lug engaging the lug on the arm it will be impossible to drive the automobile

SAFETY ATTACHMENT FOR AUTOMOBILE CRANKING MECHANISM—H C TUNIS, 54 Wakeman Ave, Newark, N J This invention provides means whereby is rendered impossible the ignition compression in engines of automobiles, while the speed gears thereof are in service position, and provides a simple and efficient mechanism for effecting the above stated operation

TIRE UPSETTER AND SHRINKER—J F BOYD, Box 25, Bigelow, Ark This improvement comprises a pair of upsetting blocks mounted to be moved toward and from each other, which carry gripping means for engaging the edge of the tire to crowd or compress the body thereof together, and thus reduce tire circumference to the required extent, and fit more tightly on the wheel The blocks are positively operated to be moved toward each other to cause the grips to perform the compressing operation, and means are also provided to return them after the operation of gripping, to their original positions

AUTOMOBILE LOCK—T S KEFFER, 22 N Raleigh Ave, Atlantic City, N J. The purpose here is to provide a lock for use in connection with the steering wheels of automobiles and other motor vehicles for preventing movement of the steering wheel by unauthorized persons, which may be applied to the steering wheel of any motor vehicle, without change in the wheel itself, and which when in operative position will absolutely prevent movement of the wheel, and when in inoperative position will not interfere with the operation of the wheel



AUTOMOBILE LOCK.

Designs.

DESIGN FOR A SANITARY TELEPHONE MOUTHPIECE—C MUNDT, 832 Willow Ave, Hoboken, N. J In this ornamental design for a sanitary telephone mouthpiece, one figure is a front view of a telephone mouthpiece, another is a rear view of the mouthpiece, and the last is a vertical section through the mouthpieces, part of a telephone being shown in dotted line

DESIGN FOR A TICKET BOOTH—W YAEGER, care of Strauss & Co, 209 W 48th St., New York, N Y In this design for a ticket booth the structure presents an elevation of exceptionally pleasing appearance Above the base a columned center supports a dome of highly ornamental design, which is crowned by a sphere.

DESIGN FOR A BUST REDUCER BRASSIERE S H BURNS and C D PERILLAT, "Ye Lady's Outfitterie," 15 W 38th St, New York N. Y In this ornamental design for a bust reducer brassière, Fig 1 is a front view in perspective; and Fig. 2 is a rear view

---

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

WE wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade mark work. Our staff is composed of mechanical electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject matter involved, or of the specialized, technical, or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade mark applications filed in all countries foreign to the United States

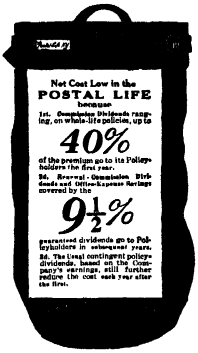
Want your share of that $60,000,000 fund?

IF you're a policy-holder in any old-line life-insurance company (except one), you've contributed to an annual fund for agency-expense which in 1912 **amounted to more than $60,000,000.**

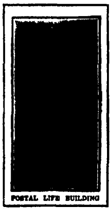
You'll never get your contribution back or any part of it—**now;** but you need never pay it out again—you can save it—if you will steer clear of life-insurance agents and deal **direct** with the **one non-agency institution in America—the Postal Life Insurance Company.**



Net Cost Low in the
POSTAL LIFE
because
1st. Commission Dividends ranging, on whole-life policies, up to
40%
of the premium go to its Policyholders the first year.
2d. Renewal-Commission Dividends and Office-Expense Savings covered by the
9½%
guaranteed dividends go to Policyholders in subsequent years.
3d. The Usual contingent policy-dividends, based on the Company's earnings, still further reduce the cost each year after the first.

THE Company's Health Bureau also performs a most important service in **health-conservation** by issuing timely Health Bulletins for the benefit of its policy-holders, and by providing for those who so desire, **one free medical examination each year**—a privilege not accorded by any other company.

It will thus be seen that **the Postal Life Saves You Money and Safeguards Your Health.**



POSTAL LIFE BUILDING

It will be well worth your while to find out just what the Company will do for you on any standard form of policy—whole life, limited-payment life, endowment, joint-life, monthly-income, or child's welfare.

For quick action simply write and say:

"Mail full insurance particulars for my age as per advertisement in SCIENTIFIC AMERICAN for April 4," and be sure to give

1. Your Full Name.
2. Your Occupation. 3. The exact Date of Birth.

The Company *will promptly send you (by mail only)* figures for your age with the amount of dividends guaranteed; also additional policy dividends now being paid, showing the Postal's low net cost.

No agent will be sent to visit you, the Company does not employ agents By dealing direct, you get the benefit of the commission other companies pay the agent.

POSTAL LIFE INSURANCE COMPANY
WM R. MALONE, President
35 Nassau Street New York

STRONG POSTAL POINTS

First: *Standard policy-reserves*, now nearly $10,000,000. *Insurance in force* nearly $50,000,000

Second: *Old-line legal reserve insurance*—not fraternal or assessment

Third: *Standard policy-provisions*, approved by the State Insurance Department

Fourth: Operates under *strict State requirements* and subject to the United States Postal Authorities

Fifth: *High medical standards* in the selection of risks

Sixth: *Policyholders' Health Bureau* arranges one free medical examination each year, if desired

UNDERWOOD
"The Machine You Will Eventually Buy"

Fighting Dust With Dust

(Concluded from page 290.)

as is laid down in the above clause would be taken, in our opinion, if the roads were treated with incombustible dust.

"It should be clearly understood that in recommending this limit of 50 per cent of ash we are putting it forward provisionally and as a minimum."

In closing this brief account of the present position in the United Kingdom with regard to the use of stone dust in mines, a few particulars of the Experimental Explosion Station at Eskmaels, in Cumberland, may be given, also some details of the constitution of the committee in charge of the experimental work.

The experiments were commenced by the Mining Association of Great Britain, at Altofts Colliery, Normanton, Yorks, in 1908. The result of these experiments was to prove beyond all doubt the truth of the theory that coal dust suspended in the air was capable of being ignited without the aid of any inflammable gas, and was, therefore, capable of propagating an explosion through the dusty galleries of coal mines.

The official record of these experiments, and of the conclusion based upon them, is contained in the *Proceedings* of the Mining Association of Great Britain, for the year 1910. In that year, the Mining Association approached the Royal Commission on Mines with the view of ascertaining whether the government would be prepared to continue the experiments at the public cost, and offered to lend to the government the experimental plant and apparatus that they had accumulated at Altofts. This proposal was communicated to His Majesty's government, which ultimately undertook to find the funds necessary for the purpose An executive committee to carry out the experiments was appointed by the Secretary of State for the Home Department, consisting of Sir Henry Cunynghame, chairman; Mr R. A. S Redmayne, Capt A H P Desborough, Prof H B Dixon, and Mr W. C Blackett. The members of the Royal Commission on Mines, together with the Coal Dust Committee of the Mining Association already referred to, were constituted as a Consultative Committee The first meeting of the Executive Committee was held at the Home Office on May 11th, 1911.

The site at Altofts being no longer available, it became necessary to seek a new one. An endeavor was made to secure a suitable locality which should be at a fairly equal distance from the various coal fields in England, Scotland, and Wales, which should be remote from dwellings, and at the same time should be near a railway so as to afford convenient access for heavy material. After the examination of numerous sites a piece of land on the sea was chosen, near Eskmaels, in the county of Cumberland, adjoining the gun-range of Messrs. Vickers The works are surrounded by sand hills. The space available for a gallery measures 600 yards in length from the eastern side of the seashore. The large gallery (7 feet 6 inches) has been removed from Altofts, and has been placed east and west, so as to point seaward, and it nows extends to a length of 800 feet.

A smaller gallery, 3 feet in diameter and 400 feet long, has been fixed alongside the large gallery for the purpose of making comparative experiments, and the number of recording instruments for following the course of the explosions has been accordingly increased.

The writer's thanks are due to Prof. Harold Dixon, F.R.S., a member of the Home Office Committee, in charge of the experimental work, and also to Dr. Wheeler, the chemist in charge of the tests at Eskmaels, for their co-operation in obtaining photographs and information for use in this article.

The Water-drop as a Microscope

(Concluded from page 288.)

the lens, thus limiting the diameter of the hole, which can successfully be used to hold the drop, and the magnifying power of the lens possible with any given holder. The magnifying power may, however, be increased by using a smaller holder, since

the surface of the drop will be sharper and the effect of gravity is lessened. Very small holders are to be avoided, especially in photographic work, as they let through too little light. Of course it is necessary to use the holder in a horizontal position.

The simplest and best type of holder is that shown in Fig. 2. It consists of a piece of metal about 1/32 inch thick having a straight round hole bored through it at the center. It is of paramount importance that the upper and lower edges of this hole be true circles. The easiest way to insure this is to drill the hole with a first-class twist drill, and then polish both top and bottom surfaces on a flat oil stone. If iron is used it should be blued afterward by heating, to prevent rusting. The best results with this type of holder are obtained with a diameter of from 1/16 inch (having a maximum magnifying power of 100 diameters) to ⅛ inch (having a maximum magnifying power of 60 to 70 diameters).

To fill the holder, a stick with a very long, slender point is best. Dip this stick in the liquid, shake off any surplus, place the point against the inner surface of the holder and allow the desired quantity of liquid to run in. Considerable care must be exercised to prevent any liquid from running over the surface of the holder, thus destroying the circular contact. No trouble will be experienced in this respect unless too much liquid remains on the stick, or its point is allowed to slip over the surface of the holder.

Fig. 3 shows the apparatus used in taking the accompanying photographs. It consists of a camera *A*, whose lens has been replaced by a wooden frame supporting the holder *B*, so arranged that the holder may be easily removed for replacing the liquid lens. The camera is supported on an upright *C*, fastened to the box *D*. Within the box *D* is a lamp *E* and the camera lens *F* so placed as to concentrate the light on the liquid lens in *B*. The adjustable platform for bringing the slide *H* into focus consists of the board *G* pivoted at one end and supported by the screw *S*. Focusing is accomplished by turning the screw *S*, which should be capable of a vertical adjustment of at least ⅛ inch, and should make it possible to bring the slide *H* nearly into contact with the liquid lens. The box *D* and the platform *G* have holes in them directly under the liquid lens to let through the light from the lamp.

The image of the specimen is projected by the liquid lens against the ground glass of the camera and sharply focused by turning the screw *S*. When this has been done, the camera is loaded in the usual way. An exposure of 5 minutes with an ordinary kerosene lamp burning half height will probably suffice.

In photographic work, instead of water, it is best to use a glycerin lens, as a glycerin lens will not change its focal length by evaporation, and is not easily shaken by small jars.

For use as a microscope, the apparatus shown in Fig. 4 is sufficient. *M* is a mirror, *L* is the lens holder, *P* is the adjustable platform for holding the slide, and is made like *G* in Fig. 3. The mirror is tilted so as to reflect the light from any source up through the slide. If much field is desired, the eye must be placed quite near the liquid lens.

With this simple apparatus the hairs on the edge of a fly's wing, the teeth on the edge of a blade of grass, wood cells, etc., are distinctly visible; in fact, this simply constructed liquid lens microscope is sufficiently powerful for the needs of most amateur naturalists.

Commissioner Ewing and the Patent Office Building

IN a statement before the Committee on Public Buildings and Grounds of the House of Representatives, Commissioner Ewing has many interesting things to say about the Patent Office building. In the first place, he points out that the Secretary of the Interior occupies about three fourths of the room in the basement and about one half of the rooms on the main floor, and suggests that if the Secretary of the Interior were removed out of the

How Would You Better This Car?

1914 MOON Light Weight Six-50

⁋You've got to judge a car by its parts and by the way those parts are *blended* into a whole.

⁋Now, [illegible]e are the main part featu[illegible] of the Moon Light Wei[illegible] Six-50.

⁋The [illegible]ntinental Motor Co. buil[illegible]e Motor. It is the best they [illegible]n build, their latest pro[illegible]t and built especially for [illegible] You know what "Continel[illegible]" stands for.

⁋This [illegible]tor is built to embody the *D*[illegible] Starting and Ignition system. Can you suggest a superior system?

⁋Then, the motor is built to take our tire pump—an up-to-date car without a tire pump would be a good deal like a Solid Vestibule Train without a Dining Car.

⁋We use the four speeds ahead and reverse Warner Transmission—can this unit be improved upon?

Note These Moon Features:

Patent Office building there would then be not more than room enough to provide for transferring from each examining division the men and women who ought not to be there as a mere question of sanitation, or in the language of the Commissioner, "If we had the whole building it would not be adequate to our purposes, for the building is not large enough as it stands." He refers to the storage necessary for bundles of each of the one million one hundred thousand patents already granted, making a total of forty-seven million copies of patents. The income last year from the sale of copies of patents being $115,000 with a cost of handling the patents of from $15,000 to $20,000, leaving an income of about $95,000 a year net from the sale of patent copies. The 47,000,000 copies of patents being scattered over the building from garret to cellar, so that were a fire to get started, they would unquestionably be destroyed. In urging a new building the Commissioner says: "I want to say that I do not intend to insist that we have got to have a new building in order to do the work better than we are doing it, because we are going to do the work better than we have been doing it, but, as a matter of fact, the crude conditions are extremely bad for the efficiency of the work." Referring to the surplus earned by the Patent Office, the Commissioner pointed out that the Patent Office received last year $137,000 more than it spent, and expressed the belief that this year it would receive more than $200,000 above what it spent, and suggests that while it is proper that the business of the inventors should be paid for by them, it is equally proper that what they do spend should be paid out in giving them a proper return, and that it is to the public's benefit as well as to that of the inventor that the work should be done as well as it can be done. In answer to a question by Congressman Bell of the Committee the Commissioner said that he did not feel that the public were receiving what they should in the way of accommodation and otherwise for the money they are paying, and that they are not only not receiving prompt service, but they are not receiving complete service or efficient service.

First Magnitude Stars

(Concluded from page 280)

suns. All these then are blazing orbs, of which the faintest, substituted for our sun, would flood us with twice its light, and the brightest with 10,000 times the same

While the sizes of the fixed stars cannot be measured because of their distances, some estimate of the same may be justified by the light which they possess, even while making due allowance for possible variations of surface brilliancy. In general we cannot but regard the first magnitude stars, as compared not only with earth, but even with the sun, as being giant worlds of the first order. Arcturus alone has been thought to have a diameter 100 times that of our sun, which in turn is 108 times that of the earth.

In the matter of distance, most of these stars are within that degree of proximity which enables them to yield a parallax, by reason of the earth's shift of position, from one side of its orbit to the opposite, every six months There are only about 300 such stars known Larger and brighter stars there probably are, so distant that they are dimmed by the enormous gap which separates them from us and leaves us ignorant as to how remote they really are. The nearest of all the stars, so far as measured, is the third of the first magnitude, namely, Alpha Centauri, which requires 4.3 years to send us its light, while our own sun's comes in 499 seconds, or about 8½ minutes. Sirius is twice this distance, and is the third nearest star to earth, to which its extraordinary brilliancy is to be referred, rather than to its size or inherent splendor, great as these doubtless are. Four of these are numbered among the twelve nearest stars to earth, namely, Alpha Centauri (first nearest), Sirius (third), Procyon (sixth), and Altair (twelfth), the latter requiring only 14 years to send us its light.

As we follow through the list, more and

Only 2 Cylinder Rowboat Motor MORE POWER GREATER SPEED

Here's the latest, finest thing in detachable rowboat motors—beats anything on the market. A real engine, Powerful, fast—quiet and smooth running. Starts on the first "Kick" and reverses easily.

KOBAN ROWBOAT MOTOR

Overcomes vibration, the biggest objection to rowboat motoring. All revolving and reciprocating parts perfectly balanced Fits any rowboat—can be steered with engine shut off Cost less per horse power. Valuable Books

Scientific American Reference Book
EDITION OF 1914.
Compiled and Edited by ALBERT A. HOPKINS and A. RUSSELL BOND. 12mo., 597 pages, 1000 illustrations. Price, $1.50.

¶ A handy, compact, reliable and up-to-date volume for everyday reference, containing a remarkable aggregate of facts, statistics and readable information along industrial, commercial, scientific and mechanical lines of interest to everyone. This volume is a revelation in the nature of facts and figures relating to population, manufactures, commerce, railroads, shipping, mining, agriculture, education, aviation, armies and navies of the world, Panama Canal, post office affairs, telephony, telegraphy and wireless telegraphy, patents and copyrights, chemistry, astronomy and time, meteorology, mechanics, weights and measures, and thousands of other subjects. It will prove invaluable on the desk of the business man as well as the library of the home. No expense or effort has been spared to make it interesting as well as authoritative.

Practical Pointers for Patentees
By F. A. CRESEE, M. E., 5 x 7¾, cloth, 146 pages, $1.00.

¶ This is the most practical, up-to-date book published in the interests of patentees and sets forth the methods employed by the most successful inventors in handling their patents. It is written expressly for patentees by a practical inventor and is based upon the experience of some of the most successful inventors of the day It gives exactly that information and advice about handling patents which is needed by every inventor who would achieve success.

Wireless Telegraphy and Telephony Simply Explained
By ALFRED P. MORGAN. 12 mo., 154 pages, 156 illustrations Price, $1.00

¶ A popular, practical and simply worded treatise embracing complete and detailed explanations of the theory and practice of modern radio apparatus and its present-day applications. The author has filled a long-felt want and has succeeded in furnishing a lucid, comprehensive treatise for the operator, both amateur and professional. A close study of its pages will enable one to master all the details of the wireless transmission of messages and to design and construct his own apparatus. Although based on scientific principles, no attempt has been made to give mathematical explanations It is written so that it can readily be understood by men who are not technical and at the same time is sufficiently comprehensive and practical to be studied advantageously by the ambitious young engineer or experimenter.

Any of these books will be sent postpaid on receipt of advertised price

NEW YORK CITY

PATENTS PROTECTED BY THE PATENT TITLE AND PROTECTIVE CO. NEW YORK

[illegible] in space do we find surprising [illegible] 49 light-years for Capella, 90 for Regulus, 112 for Antares, then a strange and enormous gap to nearly or more than 500 for several others, including the magnificent Canopus. It seems strange that the twentieth star is much nearer than the second. What these distances mean is made clearer when we learn that, to travel to the nearest of all the stars, namely, Alpha Centauri, at the rate of 60 miles an hour, would require 49 million years, with an extra 100,000 years disregarded.

As for the location of these brilliant stars in the heavens, the reader is referred to the star atlases. Of the 15 seen by us northerners, 9 are visible in spring, 6 in summer, 6 in autumn, and 9 in winter. Only Rigel and Betelgeuse are found by northerners in the same constellation, namely, Orion, to whose extraordinary brilliancy they contribute not a little. The others are single gems in the constellations which they adorn.

It should be added that eight of these first magnitude stars have companions, whose brilliancy alone runs from 1/2,000 that of our sun in the case of Procyon's companion, and 20 times that of the sun in the case of Rigel's, to 200 times the same in the case of Beta Centauri's, which latter star alone has a brilliancy of 350, making its total brightness 550 times that of the sun. No other first magnitude star boasts of a companion with a brightness of more than one tenth of that of the companion of Beta Centauri.

TABLE OF FIRST MAGNITUDE STARS

The Electrolysis of an Egg

By Albert A. Somerville

SUPPOSE the ends of an egg are punctured, so as to admit small wires, and that by means of these two lead wires the egg is made a part of an electrical circuit, all of which is easily done. Now the electrical resistance of the egg may be measured in ohms, *probably*. Then if the terminals are connected to a power circuit, current may be sent through the egg and thereby generate sufficient heat to cook it, *possibly*. Now that egg is neither fried, boiled, poached nor scrambled. If it is cooked at all, will someone be so kind as to suggest a name for it to put on a bill-of-fare in some Broadway café? Someone has suggested that it might be known as an electrocuted egg. This would probably apply better if there were a chicken inside.

The body of an egg consists primarily of a great mass of albumen. When the contents are decomposed by time or by an electric current there is formed a large volume of gases, principally nitrogen, hydrogen, and oxygen.

The shell consists mostly of carbonate of lime, and may be so nearly colorless or translucent that the contents of a fresh egg show a pinkish blush through it.

The idea of the investigation was to cook the egg by sending current through it, its own resistance causing the requisite heat to be generated upon passage of the current.

It is well known that the amount of heat generated per unit of time in an electrical circuit is proportional to the current flowing multiplied by the electromotive force, or stated another way, is proportional to the product of the current squared and the resistance. Also it is known that great progress is being made along the line of electrical heating for scientific, commercial and domestic purposes. Even though the efficiency is fairly high the expense of electrical heating is considerable, and as yet the only thing to recommend it is its cleanliness and convenience. For scientific and commercial work, where very high temperatures are desired, arc furnaces are used principally. In domestic use, where only moderate temperatures are required, the resistance type of heater is used, the resistance unit formerly being wound with some pure wire, and more recently with some alloy having smaller coefficients of variation with temperature change. That is, if the length of the wire is nearly constant at all temperatures it is easier to [illegible] and hold it in place, and if the resistance is nearly constant the variation in current is easier to control.

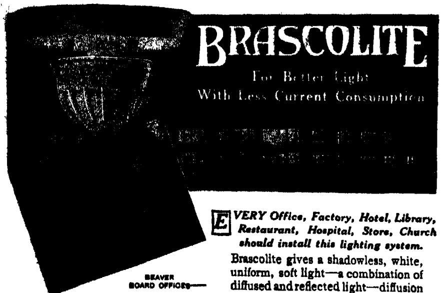
If a heater is to be made, the resistance is adjusted so that if connected to a certain common voltage a certain temperature will be attained in a specified time. All the heat generated or nearly all has gone into the heater, but even from there not more than half of it gets to the desired point where the heat is to be applied in the case of most heating appliances, and it is only in a few cases that the heating unit can be located within the thing to be heated so as to utilize practically all of the heat to advantage.

If the thing to be heated could itself be made the conductor to carry the current and to offer suitable resistance to the same, then all the heat would be generated within the body to be heated and the efficiency would approach 100 per cent as soon as possible.

A 16 candle-power incandescent carbon lamp measures about 220 ohms and draws ½ ampere on a 110-volt line. If placed in a vessel containing water it will bring a pint of water to the boiling point in a very reasonable time. Instead, however, of using the lamp as a heater two terminals may dip into the water when properly prepared and the resistance of the water itself may be used as the heating unit instead of a wire coil. The resistance of the human body is said to be anything from 5,000 to 15,000 ohms, so that of a slice of meat ought to be something within the hundreds, and if placed between two metallic plates or conductors connected to a line or proper voltage, such a slice of meat should be cooked by means of the current by virtue of its own resistance.

The electrical resistance of a loaf of baker's bread taken from end to end is about 2,000 ohms, so the resistance crosswise of a slice of the same is about 100 to 200 ohms, as readily measured by a Wheatstone bridge method. If a slice were placed between the two metallic plates connected to proper voltage it should be nicely toasted, and then since toasted bread is an insulator, it should automatically cut off current when it is thoroughly toasted or done.

In all these cases all the heat is generated in the thing itself which is to be heated, so very little heat is lost. The method was actually tried upon an egg in the manner indicated in the opening paragraph. Three distinct steps were made in the experiment. It was necessary to know



BEAVER BOARD OFFICES—
THESE PHOTOS ARE NOT RETOUCHED—TAKEN WITHOUT FLASHLIGHT—JUST BRASCOLITE.

EVERY Office, Factory, Hotel, Library, Restaurant, Hospital, Store, Church should install this lighting system.

Brascolite gives a shadowless, white, uniform, soft light—a combination of diffused and reflected light—diffusion from the bowl and reflection from the depolished white plane of the fixture itself. Note that the ceiling of the room is not depended upon for reflection—the fixture, as it were, carries its own ceiling. It has been proved by Photometric Tests that the Brascolite System is more efficient than direct reflected light and 50% more efficient than indirect lighting—yet one gets all the eye ease and diffusive benefits of the indirect system.

¶ The best way to know Brascolite is the intimate way—day to day and night to night, your own personal experience with it. That will best teach you what it will do for you in your business or professional connections—so—

Put a Brascolite
In Your Library, Billiard Room

in your hall or vestibule or in your private office. Then note the quality of the light—the *completeness* of the illumination—every part of the room bright—no "spots of light," no shadowy corners. To make the experiment costless to you we will make this proposition—have your dealer install a Brascolite for you—

Try It For 60 Days

If not satisfied at end of that period return it and get your money back. And further—IF satisfied and use convinces you that it is needed in your business; when order is received by your dealer for business equipment totaling $100 00 or more he is authorized to refund to you the purchase price of your personal trial light.

Check Off on List Below

Business You're Identified With and your official connection and mail to us so that we may send you specific information relative to Brascolites and what their installation will mean in light improvement and economy for you and your business. If your official position is other than indicated write title on blank line

JUST ISSUED!—*New, Revised and Enlarged Edition, Showing All Recent Improvements*

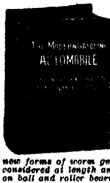
The Modern Gasoline Automobile

Its Construction, Operation, Maintenance and Repair

By VICTOR W. PAGÉ, M.E.

Covers Every Phase of Modern Automobile Practice. Latest and Best Treatise

Over 800 (5½ x 8) Pages 575 Illustrations Price $2.50 *11 LARGE FOLDING PLATES*



The latest and most complete treatise on the Gasoline Automobile ever issued. Written in simple language by a recognized authority, familiar with every branch of the automobile industry. Free from technical terms. Everything is explained so simply that anyone of average intelligence may gain a comprehensive knowledge of the gasoline automobile. The information is up to date and includes, in addition to an exposition of principles of construction and description of all types of automobiles and their components, valuable money-saving hints on the care and operation of motor cars propelled by internal combustion engines.

TO THE 1914 REVISED EDITION

Entirely new material has been added on tractors in three and four wheel forms, cyclecars and agricultural tractors or automobile plows; combination gasoline-electric drive, front-wheel and four wheel drive and steer systems and other important developments in power propelled vehicles. The discussion of power transmission methods has been augmented by consideration of the skew bevel gear and two-speed direct drive rear axle, as well as several new forms of worm gear drive. The subject of electrical motor starting systems has been considered at length and all leading systems and their components described. A discussion on ball and roller bearings, their maintenance and installation, has also been included, and a number of other features of timely interest such as latest types of gasoline and kerosene carburetors, cyclecar power plants, the Fischer slide valve motor, detachable wire wheels, etc., have been added to bring the work thoroughly up to date.

The book tells you just what to do, how and when to do it. Nothing has been omitted, no detail has been slighted. Every part of the automobile, its equipment, accessories, tools, supplies, spare parts necessary, etc., have been discussed comprehensively. If you are or intend to become a motorist, or are in any way interested in the modern gasoline automobile, this is a book you cannot afford to be without.

THIS BOOK IS SUPERIOR TO ANY TREATISE PUBLISHED
IT IS RIGHT UP-TO-DATE AND COMPLETE IN EVERY DETAIL

Not too Technical for the Layman—Not too Elementary for the More Expert

Sent prepaid to any address on receipt of price

The Sharpening Stones You Can Depend Upon

ALWAYS free and fast cutting—uniform in their texture, holding their shape, and showing almost as long a life as your tools.

Carborundum
Sharpening Stones

Have earned a place in the tool kits and on the work benches of users of edge tools everywhere. There is nothing harder, sharper, or faster cutting than Carborundum.

There is a Carborundum Stone for Every Sharpening Job.

From Your Hardware Dealer or Direct.

The Carborundum Company
Niagara Falls, N. Y.

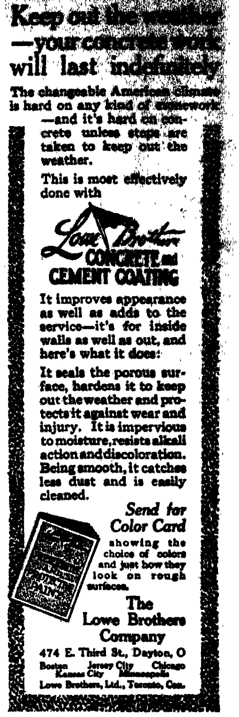
whether or not the contents of an egg would carry a current or whether it was a high insulator, or if not, what its electrical resistance would measure. For this first part, small holes were pricked in the opposite ends of a fresh hen's egg, small copper wires inserted through these holes to a depth of a quarter of an inch or more, and these wires connected to the Wheatstone bridge. The resistance of the egg would then be measured just like any other unknown resistance. When the circuit was first closed and the bridge balanced a resistance of about 1,000 ohms was indicated, but this resistance slowly and steadily increased for several minutes until its former value was more than doubled. If the circuit was broken for a few minutes and then closed again, the original resistance was regained and the same change was executed as before. This could be repeated many times. Only one or two volts of electromotive force was being used, and it was thought that this change in resistance was due to some change taking place at the terminals, which would be overcome by using a higher voltage.

The terminals were accordingly connected onto a 110-volt direct current supply, with an ammeter and voltmeter in circuit so as to measure the resistance by means of the relations $C = \frac{V}{R}$ or by what is known as the "potential drop" method.

When the circuit was first completed the ammeter registered about one tenth of an ampère, thus indicating the proper resistance of approximately 1,000 ohms. Shortly, however, the current began to decrease, indicating an increase in resistance, the potential drop remaining constant, and this increase in resistance went on much faster than when only one or two volts were used in the Wheatstone bridge method.

The current decreased until almost inappreciable. The holes in the ends of the egg where the lead wires were introduced had automatically sealed themselves on standing several hours, so that the egg might ordinarily have been considered intact or air-tight. You have heard of people sweating blood This egg began to sweat albumen. Literally the white of the egg was being forced out through the pores of the shell Practically everything is porous. Water can be forced through the walls of an iron vessel if sufficient pressure is brought to bear upon it. An egg shell is porous. That is the reason for coating eggs with paraffine to prevent air leaking in and so allowing the egg to decay. It is by means of these same pores that the chick receives its oxygen to breathe. Since the white was being forced out through the pores in the shell some pressure must have been brought to bear on the inside. This might be due to heating, but the current was so small by this time that there was no appreciable heating.

Another idea would be that the formation of gas, due to the decomposition of water into hydrogen and oxygen, was the cause of the pressure. One would at first think that these gases would have been forced out through the pores of the shell rather than the white of the egg, but probably both gases and white went out together, the gas carrying small particles of the white with it Finally after about an hour nearly all the white of the egg was forced on the *outside*, the 110 *volts* having been on all this time, the current being measurable only in hundredths of an ampère. Suddenly there was a spark and an explosion—it seems that the hydrogen and oxygen had been separated by the current and the gases formed, after forcing most of the white of the egg out of the shell, had then circulated around until the resistance broke down at some point, allowing a spark to pass, and so set off the gases which were present in the right proportion to produce a good explosive mixture. Anyone who has ever seen a mixture of hydrogen and oxygen exploded in a glass flask may have just a slight idea of what happened when the gases in that egg shell exploded. Only a deep-sea diver's suit could have protected a man from the spattering.



Keep out the weather
—your concrete work will last indefinitely

The changeable American climate is hard on any kind of stonework—and it's hard on concrete unless steps are taken to keep out the weather.

This is most effectively done with

Lowe Brothers CONCRETE and CEMENT COATING

It improves appearance as well as adds to the service—it's for inside walls as well as out, and here's what it does:

It seals the porous surface, hardens it to keep out the weather and protects it against wear and injury. It is impervious to moisture, resists alkali action and discoloration. Being smooth, it catches less dust and is easily cleaned.

Send for Color Card showing the choice of colors and just how they look on rough surfaces.

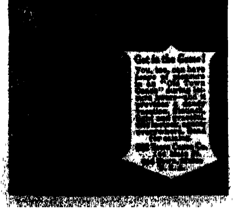
Carnie-Goudie Mfg. Co., 114 A Street, Kansas City, Mo.



It was then decided to use an alternating instead of direct current in the hopes that this decomposition would not occur. Also, it was possible to obtain higher voltages from the alternating current supply. It was accordingly tried with these results. Voltage was varied from 175 to 235 and 575 volts, successively. The current remained at 0.1 ampère for some time, and finally gradually decreased at the higher voltage to about 0.01 ampère. Evidently the egg became to some extent a rectifier. At one terminal only there occurred continuously a series of very small explosions which could be distinguished from the ordinary sparking, which sparking made the egg beautifully translucent throughout. It was also accompanied by a very distasteful odor not unlike that of decayed eggs or burning horn. Since there was no cooking whatever it was thought best to call the experiment that of "The Electrolysis of an Egg."

Motion Pictures of Vocal Chords

By Jacques Boyer

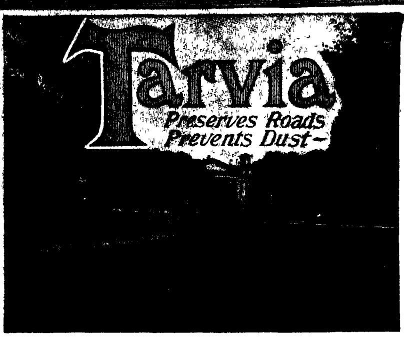
ALL vocal sounds originate in the larynx, where the breath is forced through a slit formed by two membranous cartilages, which are popularly known as the vocal chords. These cartilages approach and recede from each other, thus varying the width of the slit, and they are thrown by the outrushing air into vibrations of greater or less rapidity, which are communicated to the air current which has excited them. The buccal cavity, comprised between the glottis and palate and the lips, acts as a resonator, reinforcing certain harmonic components of the original complex vibration and giving the sound its particular vowel quality, while the consonants are produced by movements of the tongue and lips. In other words, the voice results from a laryngian vibration modified by the cavity of the mouth and other supra-laryngeal resonators.

The exceedingly rapid aerial vibrations which constitute spoken words—from 80 to 1,000 vibrations per second—were photographed by Dr. Marage, years ago, and now Mlle. Chevroton and Mons. F. Vlès, with the collaboration of Mme. Marage, have obtained motion pictures of the movements of the vocal chords. These experiments are so delicate and so irksome to the subject that they had scarcely been attempted before with human subjects. Czermak, Stein, French, Wagner, Brown, Blucke, Cadett and others had endeavored to photograph the glottis in fixed positions, but had obtained only mediocre results. Garel alone had succeeded in producing good stereograms of the vocal chords.

Mlle. Chevroton and Mons. Vlès solved the problem by placing in front of the camera two isosceles right angled prisms connected by their hypotenuses. The rays of an electric arc, made parallel by a lens, are reflected along the axis of the camera to the throat of the subject by one prism, and the rays emitted by the glottis, thus illuminated, pass along the same axis through both prisms to the camera. This invariable relation between the illuminating and the effective rays facilitates the management of the laryngoscope, the position of which relative to the photographic field can easily be rectified by means of a total reflection prism placed behind the film.

From a study of the cinematograph films thus produced it appears that most parts of the larynx contract in passing from respiration to voice production. In general, the maximum width of the vocal chords coincides with their maximum apparent length, and their phases of repose and of widest separation, during inspiration. The sharpest photographs are obtained at these epochs. The measurements of the length of the vocal chords possess less interest, as the part played by each element in the change of length is not known, and the shortening of the chords is marked by the movements of the epiglottis and cricoid and by a general contraction of the uppert part of the larynx.

On the other hand, the minimum width of the vocal chords coincides with their minimum apparent length and their phases of sound emission and closest approxima-



Road south front of White House, Washington, D C Constructed with "Tarvia X"
Showing U. S. Treasury building

In front of the White House

The roadways leading to the White House, U. S. Treasury and State, Navy and War Departments, in Washington, illustrated above, were constructed with "Tarvia X" in 1911.

The above photograph shows the condition of these roadways two years later. They are quiet, clean, smooth and dustless, entirely suitable for so exacting a location.

The Tarvia forms a tough matrix around the stone, holding it firmly in place. Automobile traffic simply rolls down the surface and makes it smoother.

The maintenance cost of tarviated roads is insignificant, and their first cost is only slightly higher than that of ordinary macadam. Tarvia has no odor and does not track.

Tarvia is made in three grades—"Tarvia X" is a dense, viscid coal tar product of great bonding power, suitable for building Tarvia-macadam roads; "Tarvia A" and "Tarvia B" are thinner grades suitable for roads already in use, to preserve them and make them dustless.

Booklets free on request.

"The Problem of Our Navy"

A Series of 10 Comprehensive Articles

on the present condition of our Navy, showing its unpreparedness, its present rating among the navies of the world, and what must be done to bring it up to its proper strength and position

Published Consecutively in the Scientific American

Five articles of this series have appeared in the issues: February 28th, March 7th, March 14th, March 21st and March 28th

These five Copies sent to any address in the United States for 55c in stamps

No. 1—"How the Navy is Daily Employed"—by *Hon. Franklin D. Roosevelt, Asst. Secy. of the Navy.*
No. 2—"Sea Power and Our Foreign Policy."
No. 3—"The Decline of the United States Navy to Third-Class Rank."
No. 4—"The Price we Pay for Self-Sufficiency and Unpreparedness."
No. 5—"Battleship Strength Necessary to Guarantee Peace."

The 6th article appears in this issue

No. 6—"The Shortage of Scouts, Torpedoes and Mines."
No. 7—"The Shortage of Officers and Men."
No. 8--"The Need of a System of Rapid Mobilization."
No. 9—"The Need of a Council of National Defense."

The 10th and concluding article will be written especially for this series by Hon. Josephus Daniels, Secretary of the Navy

MUNN & COMPANY, INC. 361 BROADWAY, NEW YORK power!

Power—unbounded power—is the dominant characteristic of the Continental motor.

Upon a massive block in the testing laboratory a Continental Six, working through the only electric dynamometer of its kind in the world, at the same time records its own power and transmits it, in the form of current, for the operating of 15 valve seating machines, a piston grinder and 2 lathes in an adjoining department. Thus its power, tested and proved, goes to fashion parts more economically for fellow Continentals.

Continental Motors

Such power is the product of correct design executed with a marvelous precision and gauged with a marvelous exactness. By tests like these a horsepower is assured to every Continental considerably in excess of its standard rating.

Power makes the performance of a pleasure car a matter of pride; of a commercial car a matter of greater profit. One may seldom need all the power of a Continental for hill or mud or sand, but one knows it is there at all times in reserve, lengthening the life of the motor and sparing every other part of the car from the vibration and clatter of constant gear shifting, and the rack of over-exertion.

Under 92 manufacturers' names, in the best motor cars and motor trucks, this Continental power may be had. Choice is not limited—satisfaction is certain.

MITCHELL KENNERLEY Publisher, NEW YORK

tion. At these instants the photographs are least sharp, because of the rapid vibrations of the chords. According to the experiments of Prof. Franck of the Collège de France, the limits of physiological variation in width of the vocal chords of a soprano are 3.2 millimeters (0.126 inch) and 1.4 millimeters (0.055 inch).

In the transition from inspiration to phonation or, more generally, during any sudden and profound change of position, the vocal chords appear to be the seat of vibrations of great amplitude and brief duration which produce multiple images of the source of light in the little mirror of the laryngoscope. This phenomenon, which affected only one of the chords and continued only from 0.1 to 0.8 second, was probably caused by a lack of synchronism in the movements of the various muscles involved in the change of position, the still lax chords being violently shaken either directly by the muscles or indirectly by variations of air pressure produced by their movements.

This novel application of cinematography will doubtless throw light on more than one hitherto obscure point in the physiology and pathology of the larynx.

How Scientists Are Studying the Aeroplane

(Concluded from page 285.)

stallation. This transportable testing plant mainly consists of a light carriage traveling on rails, which is driven by the propeller itself, actuated in its turn by a 60 horsepower automobile motor. All measurements are recorded automatically. The propeller shaft arranged about 3.5 meters above the track is so combined with a parallelogram that the whole system is free to move in the direction of the thrust, transmitted by an angle lever to a cylinder, the pressure of which is transferred hydraulically to a recording manometer. Moreover, the upper casing is free to pendulate round the propeller shaft, so that the reaction of the torque also tends to produce a deflection, transmitted to the same recording manometer

A special branch of meteorological work, *aerology*, has been formed of late years, mainly with a view of investigating the higher strata of the atmosphere, which are important for aerial navigation.

The Royal Aeronautical Observatory conducted by Prof. Assmann is situated at Lindenberg on a hill dominating the surroundings, at 65 kilometers to the southeast of Berlin. It comprises in addition to the laboratory-rooms, a small balloon hangar and a rotatable capstan house erected on the top of the hill, whence kite and balloon ascents are made; further an electrical power house which also manufactures the necessary hydrogen, by means of a Schmidt electrolyzer. Apart from kites and captive balloons carrying recording apparatus, there are launched pilot balloons, the course of which is followed by means of special theodolites from trigonometrical stations situated 3 kilometers apart and connected together by telephone. The wind conditions in the free atmosphere are gaged daily at 15 places in Germany by pilot balloons, and are communicated to Lindenberg, in order to be thence transmitted on in the form of collective telegrams. Special gale and thunder storm observations, according to a scheme organized by Assmann, are telegraphed immediately to Lindenberg from about 500 places, situated in North Germany, thus allowing the arrival of a gale or thunder storm, at a given place to be predetermined.

The aerological departments of other German meteorological observatories are arranged in a similar manner. The Teneriffe Observatory, which has been organized by Prof. Hergesell, mainly serves for observations of the higher atmospheric strata above the sea by means of twin balloons.

A propeller testing plant has been recently installed by the Siemens-Schuckert-Werke at Berlin-Nonnendamm on a high speed test electric locomotive traveling on a circular track 270 meters in diameter.

Interesting experiments have also been made by Prof. Donat Banki with a Blériot monoplane fixed by its front wheels on the roof of a rail-motor car, thus allowing its stability to be tested at speeds of 60 kilometers and more.

ST. NICHOLAS

IS PUBLISHING A SERIES OF ARTICLES

"Under the Blue Sky"

by E. T. KEYSER, whose vast experience of outdoor life and whose story-telling ability endear him to boys of all ages, from 10 to 70!

"Fishing Tackle for Boys," a bright, informing article, is in the April ST. NICHOLAS.

One of these articles told "How to Make and Use Bob Sleds." Interesting articles on Camping, Canoeing, Sailing, etc., will follow.

Be sure and read them!

The peerless umpire, BILLY EVANS, contributes to the April number the first article, "Freak Plays and Superstitions" of a great baseball series.

The young champion golf player, FRANCIS OUIMET, continues his extraordinary series on golf.

Take advantage of this Special Offer for the youngster you care for most

The Century Co., Union Square, N. Y.
Enclosed is $3.00 for FIFTEEN MONTHS of St. Nicholas, "the best-loved of all magazines," beginning with the March issue containing the first Ouimet article.

NEW BOOKS, ETC.

Work, Wages and Profits. By H. L. Gantt. New York: The Engineering Magazine Company, 1913. 8vo.; 312 pp.

The addition of more than a hundred pages to the first edition of this work has given Mr. Gantt the opportunity of correcting the impression that his methods are summed up in the bonus system. This is but one feature of the plan so successfully initiated by the author, and preceding this feature and forming the very foundations upon which the system rests are microscopic investigation, thorough standardization, personal instruction, and interconnected reward both to the supervisor and the workman. The illustrations used are drawn mainly from the textile industry. The results secured by the system in this industry are little short of phenomenal, as is graphically shown by the series of colored charts that form inserts to the volume. We see, for example, the time-sheet of a weave room. The workman is required to reach a certain standard of efficiency before he is entitled to a bonus; the days in which he fails to earn this bonus are blocked in with red; those on which a bonus is earned are blocked in with black. Steady improvement is noted as our eye crosses the page, until at the end of a few months red has almost entirely given place to black—inefficiency to efficiency, low earnings to high. Such actual records of achievement are attractive to the verge of conviction. Certainly they bespeak for such systems a fair trial

Industrial Chemistry for Engineering Students. By Henry K. Benson, Ph.D. New York: The Macmillan Company, 1913. 8vo.; 431 pp.; illustrated.

The student having some knowledge of elementary physics and general chemistry will find in this text a useful guide dealing with the materials, processes and apparatus commonly used in the engineering professions. The lessons take up such subjects as the atmosphere, industrial water, combustion, distillation, fuels and lubricating oils. Various products of manufacture are also described —pig iron, commercial iron and steel and their alloys, clay, cement and lime products, paving, and paint materials. Cellulose products and explosives also have their chapters. In short, the prospective engineer who follows the text with care and thoroughness will find himself possessed of a working knowledge of the chemistry of materials and processes, and an ability in the pursuit of experimental research that will go far toward solving his problems

Success with Hens. By Robert Joos. Chicago: Forbes & Co., 1914. 12mo, 234 pp. Price, $1 net.

The Back Yard Farmer. By J. Willard Bolte Chicago: Forbes & Co., 1914 12mo.; 238 pp. Price, $1 net.

Regarded as a crop, the product of our "billion-dollar industry" is in value second only to corn, and exceeds that of oats and wheat combined "Success with Hens" exudes common sense, and avoids the impossible estimates and extravagant promises that too often mar books of this kind. It instructs the tyro in the various subtleties of the occupation, details methods of equipment, hatching, brooding and feeding, considers both intensive and extensive systems of farming, and meets with practical advice the drawbacks and exigencies encountered in the business. "The Back Yard Farmer" also devotes nearly half its space to poultry, the remainder discusses plans for making the back yard pay dividends by way of the fruit and vegetable garden Hedges, shrubs, fruit trees, vines and the general beautification of the lawn and the surroundings come in for consideration, and there are hints on the keeping of bees and the care of the horse and the cow This manual also maintains a conservative tone, and its instructions are based on sound principles.

Laboratory Manual of Glass-Blowing. By Francis C. Frary, Ph.D. New York: McGraw-Hill Book Company, Inc., 1914. 16mo.; 60 pp.; illustrated. Price, 75 cents net.

The elements and processes of glass-blowing are presented with the aim of enabling the laboratory man to modify or repair his own apparatus In some situations this may mean the saving of considerable time and money. The author assumes that the reader is entirely ignorant of the art, hence his explanations are lucid and adequate

A Manual of Bacteriology. For Agricultural and General Science Students. By Howard S. Reed, Ph.D. New York: Ginn & Co., 1914. 8vo.; 179 pp.; illustrated. Price, $1.25.

Students will find, in this manual, experiments whose precise results will banish doubtful habits of thought and the consequent vagueness of understanding An added section of the work takes up fermentations caused principally by fungi. There is a large section of appendices, dealing with such subjects as sterilization, and containing tables of determinations, conversion tables, and record forms.

Boy's Book on Logic. A Talk, Not a Treatise. By William Timothy Call. Brooklyn, N. Y.: W. T. Call, 1914. 16mo.; 96 pp. Price, 50 cents.

We are inclined to think Mr. Call's pabulum a trifle too cynically flavored for youthful consumption; there is too much of the strong man's meat along with the milk for babes, but the tiny volume is marked by the author's usual aptitude for getting down to fundamentals and expressing certain forms of truth in a humorous and alluring way. We are initiated into the mysteries of faro; we [illegible] of the thin hind legs; incidentally and [illegible] we absorb a few principles of logic Every boy will be in hearty accord with Mr Call in his desire to simplify grammar—to "strip it to the buff," as he terms it. There is no law confining the perusal of the book to boys, and those of a larger growth may enjoy and profit by it.

The Climate and Weather of Australia. By H. A. Hunt, Griffith Taylor, B.A., B.Sc., and E. T. Quayle, B.A Melbourne. By Authority Albert J. Mullett, Government Printer, 1913. 8vo.; 93 pp; illustrated. Price, 5s.

This, the first published text-book on Australian meteorology, is issued under the authority of the Minister of State for Home Affairs. Under "Climate" it treats of the effect of the size of the continent on climatic variation, of the march of temperature, the barometric variation, the distribution of dominant winds, special factors of climatic influence, and the chief climatic regions Under "Weather" are discussed the characteristics of drought years, local rains, hurricanes and "bursters" Methods of forecasting are sketched, and the monograph is enriched by numerous maps of mean temperatures, heat waves, pressures, humidities, and rainfalls, by graphs of the mean monthly rainfall and of maximum and minimum temperatures for the various stations, and by charts of noteworthy hurricanes.

The South America Tour. By Annie S. Peck, M.A. New York: George H. Doran Company, 1913. 8vo.; 398 pp.; illustrated Price, $2.50 net.

The questions "What is there to see?" and "May the journey be taken in comfort?" are answered with a wealth of detail in the pages of Miss Peck's rather bulky volume She unfolds before us some of the finest scenery in the world—mountains that shame the Alps, cliffs overtopping those of the Yosemite, far-flung gardens of Allah, waterfalls among the highest and the most beautiful in the world The intermingling of strange peoples, the fascinating mosaic of ancient and modern, ruins and antiquities on the one hand and railroads and splendid city buildings on the other, call to us from the happy descriptions of the author's pen and the clear reproductions of her camera. These assure us of comfort on the way, and tempt us, if not to the actual undertaking of the journey, at least to the continuance of the personally-conducted tour by which she leads us through the pages of her attractive volume

The Home Nurse. By E. B. Lowry, M.D. Chicago: Forbes & Co., 1914. 12mo.; 224 pp. Price, $1 net.

The importance of good nursing in illness can scarcely be over-estimated. There are thousands of homes where a trained nurse cannot be employed, and where the duties of nurse devolve upon a member of the family Willing as she may be, her efforts are too often ill directed, and the physician's orders are but indifferently carried out Dr Lowry's book publishes the principles of general nursing—the care of the sick-room and the patient the observation of symptoms, and the administration of medicine, it gives instructions for nursing in special diseases—typhoid, pneumonia, etc., and cites simple remedies and modes of relief for those minor disorders and accidents which occur in every home

The Mechanical Engineer's Reference Book. A Handbook of Tables, Formulas and Methods for Engineers, Students and Draughtsmen. By Henry Harrison Suplee, B Sc, M.E. Philadelphia: J B Lippincott Company, 1913. 16mo.; 964 pp.; illustrated.

In any compilation of tables, methods and formulas, the merit of the resulting volume largely depends upon the selective judgment of the compiler With such a vast field as that of engineering, the task calls for exceptional knowledge, close valuations, and alert faculties, even though the material be limited to the mechanical section of that field This reference book has stood the test of time, and having been recently revised and enlarged, now passes also the test of timeliness Machine design is very fully dealt with, and the men of the draughting room will find in the book both general principles and detailed methods Only the more widely applicable rules and formulas are furnished Thus not the user's shoulders, but the author's, bear the burden of selection.

Village Improvement. By Parris Thaxter Farwell. New York. Sturgis & Walton Company, 1913. 16mo.; 362 pp.; illustrated

"Village Improvement" is a well-planned and informing little book dealing with all phases of town-beautification Addressed particularly to those not having ready access to libraries and hence somewhat out of touch with the progress that is being made, it teaches how, with little expense and small trouble, one may surround his home and his farm with the improvements that mean so much in convenience and in solid satisfaction. The work presents village improvement in its general aspects, and from that proceeds to specific and practical suggestions in regard to roads, greens, fountains, shrubbery, bridges and buildings. A form of constitution adapted to improvement clubs is given, and proved methods of operation are recounted very fully. Pictures of what has thus been accomplished the country over brighten the pages and add to their inspirational value.

The New Philosophy. Science of Physical Phenomena. By Calvin Samuel Page. First Explanations of Electricity, Gravitation, Repulsion, and the New Atomic Element Rex. Chicago: The Science Publishing Company, 1913.

Get the data—QUICK

Have a private telephone line direct to your file clerk, or your general office, or to any other part of your plant. You can get the facts you want while your party calling holds the outside wire. No time wasted in calling an office boy—telling him the details—having him go all the way to the clerk who has the data—risking his wrong delivery of the message—and waiting for him to get back. This happens every day, and is likely to continue until you get a

Western·Electric Inter·phone

A hand-set Inter-phone placed handily at the side of your desk, connected to another point in your office, costs but little, can be installed by one of your own men, and needs little attention. Built by the makers of all the "Bell" telephones and, therefore, of highest quality.

Put in a hand-set Inter-phone—or if you want to connect up several points in your plant, put in a multiple-station Inter-phone. Both are mighty valuable to any live business, and will pay for themselves many times over.

Write for our Inter-phone Booklet No. 49-AG
It will boost your organization's efficiency.

When were the First U. S. Postcards Issued?

Everybody knows the answer to that question.

Postcards were first issued the day before that joke was started about the postmaster reading them.

Yes, Mr. Bones, you're right, and that was some time ago, too. Proof of which is the fact that none of us believe that joke any longer.

But back in 1873—that is the year postcards were first issued–well, we hadn't heard it so often then.

And that reminds us of what we started out to tell you Two years before the first postcard was issued, Richmond Straight Cuts established a reputation as the best of all Virginia Cigarettes. It is a reputation that time and competition cannot tarnish. Quality proclaimed this reputation then, and Quality sustains it now.

Besides the regular package of 20, these cigarettes are also packed in attractive tin boxes, convenient for den, office or traveling, 50 for 40c, 100 for 75c. These larger packages will be sent prepaid on receipt of price, if your dealer cannot supply them

Notes and Queries

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12961) E. H. asks: 1. Would a 10-pound weight of iron sink to the bottom of the deepest part of the ocean, if thrown into it, or would it float at a certain depth? A An iron weight, or chain, would sink to the bottom in the deepest part of the ocean Iron is 7 7 times as heavy as water, and must sink in water The water at the bottom of the ocean is but 1-20 heavier than at the surface, since water is practically incompressible Hence there is no point at which the iron can stop and float Mere pressure does not prevent sinking The air presses upon us tremendously, but we fall readily through it, because the pressure is equal in all directions The same is the case with sinking in the water 2 If it did sink, would it gain velocity as it went deeper? A Calculation based upon theory shows that an iron weight will gain velocity as it falls in water until a depth of about 2 miles is reached after which the velocity will become uniform, and will be 321 feet per second The solution is to be found in Thomas Webster's "Theory of the Equilibrium and Motion of Fluids,' London, 1836 The quantities given above are for solid spheres, and not for other shapes 3 Is there any part of the Atlantic Ocean that is too deep to sound? A There is no place known, in any ocean, which has not been sounded The greatest depth is over 6 miles It is in the Pacific Ocean

(12962) B S asks· Please be so kind as to tell me in the Notes and Queries what are the electrolyte and electrodes of the Nodon valve and what is the efficiency of that apparatus in rectifying the 110-volt alternating current? A For a Nodon valve aluminium and lead plates are *ordinarily employed*, and ammonium phosphate for the solution Full instructions may be found for the construction in our SUPPLEMENT 1679 Another good article on this subject is to be found in SUPPLEMENT 1644, and another form of electrolytic rectifier is described in the SCIENTIFIC AMERICAN, vol 109, No 13 We send the three copies for 30 cents

(12963) B. F. C. asks: 1 In discussing latent heat as connected with making ice cream, is it proper to say that salt has an affinity for heat? Does salt have an affinity for ice or water, and what is the chemical reason why ice melts when in contact with salt? A There is no chemical action involved in the melting of salt and ice It is a simple physical fact that salt and ice melt when brought into contact with each other So, too, do many other substances Melting is always accompanied by the loss of heat—the heat necessary to melt the substances The freezing point of the solution is lower than that of either the salt or the ice It is 7.6 deg Fahr below zero and 39 6 deg Fahr below the freezing point of water The freezing point of a solution is always lower than that of the solvent. So salt dissolved in water lowers the freezing point of the water 2 What amount of rainfall would be equivalent to one foot of average snow? A The U S Weather Bureau allows one inch of water for each ten inches of snow as a fair average of dry and wet snow

(12964) J. T. E. asks. I would be glad to be informed through your paper as to the following Is there a known solid which has an electrical resistance in proportion to the pressure upon it, either by compression of the solid itself or of the contacts? A Carbon is the material for a rheostat which meets the condition which you impose, that its resistance shall vary with the pressure Plates of gas carbon are placed in a retaining box and a screw brings them into closer contact, thus increasing the current which flows through the box The plates stand upon edge, so that their weight does not add to the pressure at the bottom, as would be the case if they were laid flat piled up upon each other They are rated to carry about 125 amperes per square inch You can obtain such rheostats from any dealer in electrical apparatus

(12965) G R L. asks In the discharge of lightning, does all of the current pass from cloud to earth or is the current an oscillating one? A The discharge of the electric stress between a cloud and the earth takes place in either direction or both directions at once. An old professor of physics used to say that he had trained himself to see the flash go either way as he chose The duration of a flash is so very brief that the eye cannot take cognizance of its direction, and it may well be that one can see it go up or down as his mental association suggests The flash may also oscillate and pass many times up and down before it dies out In such a case it may be photographed as banded lightning by rotating the camera during the discharge You will find a valuable article on this subject, with illustrations, in our SUPPLEMENT 1635, price ten cents.

(12966) M. T asks: Two vessels identical in every respect concerning weight, size, volume and shape are placed on a pair of scales. One of them contains hydrogen at the ordinary atmospheric pressure, while the other vessel is a complete vacuum The weighing operation is done in air Now which of these two vessels would weigh more—the one containing hydrogen or the other? A A vessel which contains hydrogen will weigh more than one in which is a vacuum and which therefore contains nothing, whether weighed in the air or in a vacuum Hydrogen at atmospheric pressure and at the freezing point weighs 0 00562 pound per cubic foot, and that quantity is the amount which the vessel containing the hydrogen would weigh more than *the other for* each cubic foot of its contents.

(12967) E McM. asks: Is there any method of sterilizing cloth that can be used at home? One that does not ruin the material. A The simplest way to disinfect cloth is by the use of heat Cloth may be heated to 250 deg Fahr without injury, so that clothes, bedding and cloth generally can be disinfected in this way with entire safety Another method is by exposing the cloth to the action of the vapor of formaldehyde Formalin heated in a basin will give off the vapor abundantly and any cloth which is permeated by this vapor will be disinfected It does not affect the color of the cloth

(12968) R M. S asks: Cannot the gyroscope be applied either directly or indirectly to the guiding and control of an equatorial telescope, in place of clockwork? A We are not prepared to pass upon the possibility of controlling an equatorial telescope by a gyroscope It is a question of the perfection of a mechanical appliance A *gyroscope might be made to run as uniformly as* the best clock movement, in which case it could be applied to a telescope

(12969) E. S. M writes: In your answer to F D D, Query 12943, in the current issue of your very valuable paper, you do not set the gentleman right in one particular, and, as this matter proved a source of annoyance to me, I venture to suggest that you refer him to page 200 of the Nautical Almanack, where nearly the identical problem is stated thus

January 21st, Sid. Time at G M.

Noon	.	20	00	01	35
Red (None in this case)	. . .				
Add local Ast mean time . .		18	17	20	
Sid time (less 24 hours)	.	14	17	21	35

His mistake is in overlooking the fact that the Siderial Time at his place is the sum of the Siderial Time at that instant (corrected) plus his local Ast Mean Time for that instant His clock face should show the Right Ascension of his meridian, *not that of Greenwich* The figures above are taken from his data to make it a little plainer

(12970) R. B asks. Can you explain why these odd weights and dimensions were adopted for the unit of electrical resistance—the ohm? 14.4521 grammes mercury at 0 degrees, when in the form of a uniform cylinder 106 3 centimeters, having a section therefore, of practically 1 square millimeter Why not 15 grammes Hg at 22 deg Cent, 100 centimeters long, 1 square millimeter in section? It is noticed in a good many standard units, that odd figures are given For instance, the ampere, defined as electricity depositing 0 001118 gramme of silver per second Why not 0 001 gramme? A Perhaps the simplest presentation of the subject of the derivation of the electrical units to which we can refer you is in Silvanus P Thompson's "Elementary Lessons in Electricity and Magnetism," price $1 55 postpaid, found under the heading "Units" in the index The electrical units were determined and adopted by an International Congress of *Electricians*, which met in Chicago in 1893, composed of delegates from the nations of the world, officially commissioned by their governments to act in this capacity The several units are derived from the absolute or centimeter-gramme-second unit of force, the dyne Thus, a current has unit strength when its circuit bent into an arc of one centimeter radius exerts a force of one dyne upon a unit magnet pole placed at the center of the arc. There exists a unit of difference of potential between two points when one erg of work is done in bringing one unit of positive electricity from one point to the other against an equal and similar electric force And there exists one unit *of resistance* in a conductor when one unit of difference of potential will cause one unit of current strength to flow through the wire. So, too, for all the other units of the system Some of these absolute units are too large, and others are too small for practical use For this reason other units, called practical units, are employed which have definite relations to the absolute units The ampere is one of these and is one tenth of the absolute unit *of current strength*. It will deposit the weight of silver which you name This weight has been determined with minutest care So, too, the ohm is 10^9 absolute units of resistance, and it was determined with the highest accuracy The length of the mercury column was not guessed at, but is the exact quantity required, and it will have just the weight you give. Considering the enormous sums of money which are invested in electrical enterprises, the importance of the accurate measurement of electrical quantities is evident Considering that America is exporting hundreds of millions of dollars worth of electrical apparatus every year, the importance of an international agreement, upon what shall constitute the value of the units in which its work shall be rated, is also evident Our machinery should come exactly to the value set by international agreement, not pretty near to it. An ampere of exactly 0.001118 gramme of silver per second, and not 0.001 gramme, is what we ought to give.

Victor Jig Saw
For foot and power.
Will cut up to 2" thick.
Swings 24 in.

109 Fulton Street New York City

You May Crowd a CRESCENT JOINER
to the limit of capacity and the machine will do work just as smoothly as though you had not crowded it at all. Built in six sizes. Send for catalog telling all about them and describing our line of Band Saws, Saw Tables, Planers, Planers and Matchers, Shapers, Swing Saws, Borers, Disk Grinders, Variety Wood Workers.
THE CRESCENT MACHINE CO., 230 Main St., Leetonia, Ohio

WELL DRILLING MACHINES
Over 70 sizes and styles, for drilling either deep or shallow wells in any kind of soil or rock Mounted on wheels or on sills With engine or horse powers. Strong, simple and durable Any mechanic can operate them easily. Send for catalog.
WILLIAMS BROS., Ithaca, N. Y.

1 3/4 H.P. to 10 H.P.
SULTAN Gasoline Engine
Before buying an engine of any kind write for our free Engine Book and read the facts about the most complete, efficient, self-contained power plant ever designed —the SULTAN GASOLINE ENGINE.
For Factory, Garage, Household or all round usage. A Unit Power Plant. Frost-proof—no Pipes or Fittings. —all ready to run.
WHITMAN AGRICULTURAL COMPANY, 7002 So. Broadway, St. Louis, Mo.

THE SPEEDY STITCHER
Sews Leather Like a Machine
PRICE $1.00
Send for terms to Agents
AUTOMATIC AWL CO., [illegible] Hermon St., Worcester, Mass.

CLOCK MOVEMENTS
Spring motors and parts manufactured
All Kinds of Clock Repairing
MODEL AND EXPERIMENTAL WORK
LUX MODEL WORKS, Waterbury, Conn.

SETS OF CASTINGS OF MODEL ENGINES
MECHANICAL SUPPLIES AND MATERIAL of all kinds
EXPERIMENTAL AND LIGHT MACHINE WORK to order
[illegible] STREET, BOSTON

ELECTRICAL & MECHANICAL DEVICES
BUILT TO ORDER
MODELS, INVENTIONS, SPECIAL MACHINERY
BENJ. LEVI, 583 W. B'way, N. Y. City

☞ WANTED To manufacture METAL SPECIALTIES. [illegible] experience in making Dies, Tools and Special Machinery. Expert work. [illegible]

Cadillac
Standard of the World

17,298

This figure represents the number of Cadillac cars manufactured and distributed during the Calendar year of 1913.

It represents in retail selling value more than thirty-four millions ($34,000,000) of dollars.

It represents a volume of cars which, we believe, exceeds the sale, during the same period, of all other high-grade American cars combined, selling at or more than the Cadillac price.

11,000

This figure represents the number of 1914 Cadillac cars which have already been manufactured and distributed.

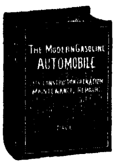
It represents in retail selling value more than twenty-two millions ($22,000,000) of dollars.

It represents a volume of cars which, we believe, exceeds the deliveries of all other 1914 high-grade American cars combined, selling at or more than the Cadillac price.

It is an unparalleled endorsement of the 1914 Cadillac.

There should be no question in your mind as to the car which dominates the high-grade field.

Cadillac Motor Car Co. Detroit, Mich.



JUST ISSUED!

New, Revised and Enlarged Edition, Showing All Recent Improvements.

The Modern Gasoline Automobile

Its Construction, Operation, Maintenance and Repair

By VICTOR W. PAGÉ, M.E.

Covers Every Phase of Modern Automobile Practice. Latest and Best Treatise
Over 800 (5½ x 8) Pages 11 LARGE FOLDING PLATES 575 Illustrations

Price $2.50

The latest and most complete treatise on the Gasoline Automobile ever issued. Written in simple language by a recognized authority, familiar with every branch of the automobile industry Free from technical terms. Everything is explained so simply that anyone of average intelligence may gain a comprehensive knowledge of the gasoline automobile The information is up-to-date and includes, in addition to an exposition of principles of construction and description of all types of automobiles and their components valuable money-saving hints on the care and operation of motor cars propelled by internal combustion engines.

TO THE 1914 REVISED EDITION

Entirely new material has been added on tractors in three and four wheel forms, cyclecars and agricultural tractors or automobile plows; combination gasoline-electric drive, front-wheel and four-wheel drive and steer systems and other important developments in power propelled vehicles. The discussion of power transmission methods has been augmented by consideration of the skew bevel gear and two-speed direct drive rear axle, as well as several new forms of worm gear drive. The subject of electrical motor starting systems has been considered at length and all leading systems and their components described. A discussion on ball and roller bearings, their maintenance and installation, has also been included, and a number of other features of timely interest such as latest types of gasoline and kerosene carburetors, cyclecar power plants, the Fischer slide valve motor, detachable wire wheels, etc., have been added to bring the work thoroughly up to date.

The book tells you just what to do, how and when to do it Nothing has been omitted no detail has been slighted Every part of the automobile, its equipment, accessories, tools, supplies, spare parts necessary, etc, have been discussed comprehensively If you are or intend to become a motorist, or are in any way interested in the modern gasoline automobile, this is a book you cannot afford to be without

THIS BOOK IS SUPERIOR TO ANY TREATISE PUBLISHED
IT IS RIGHT UP-TO-DATE AND COMPLETE IN EVERY DETAIL

Not too Technical for the Layman—Not too Elementary for the More Expert

"The Problem of Our Navy"

A Series of 10 Comprehensive Articles

on the present condition of our Navy, showing its unpreparedness, its present rating among the navies of the world, and what must be done to bring it up to its proper strength and position

Published Consecutively in the Scientific American

Six articles of this series have appeared in the issues: February 28th, March 7th, March 14th, March 21st, March 28th and April 4th.

These six Copies sent to any address in United States for 70 cents in stamps

No. 1—"How the Navy is Daily Employed"—by *Hon. Franklin D. Roosevelt, Asst. Secy. of the Navy.*
No. 2—"Sea Power and Our Foreign Policy."
No. 3—"The Decline of the United States Navy to Third-Class Rank."
No. 4—"The Price we Pay for Self-Sufficiency and Unpreparedness."
No. 5—"Battleship Strength Necessary to Guarantee Peace."
No. 6—"The Shortage of Scouts, Torpedoes and Mines."

The 7th article appears in this issue

No. 7—"The Shortage of Officers and Men."
No. 8—"The Need of a System of Rapid Mobilization."
No. 9—"The Need of a Council of National Defense."

The 10th and concluding article will be written especially for this series by Hon. Josephus Daniels, Secretary of the Navy

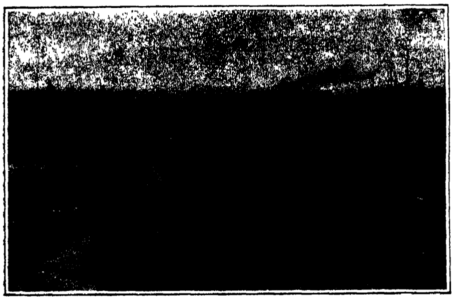
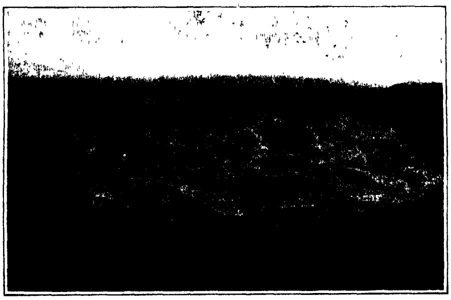
"Cathedral cut" at Chuquicamata.

One of the more extensive excavations.

A native ore concentrator.



The port of Tocopilla, where the 40,000-kilowatt plant is being built.



The deposit honeycombed with burrows of individual miners.

A Mountain of Copper

EIGHTY-SIX miles inland from the Chilean port of Tocopilla, a mountain rises to an elevation of 9,500 feet. This is not a remarkable height for a country that lies under the shadow of the Andes and yet the mountain is a conspicuous landmark for miles around because of its bright copper green color; for here is the great copper deposit of Chuquicamata, one of the largest copper deposits in the world. It covers an area 8,000 feet long by 500 to 1,200 feet in width, and the borings so far made indicate that it must contain at least two hundred million cubic yards of copper ore. What such a quantity means we can gather by comparing it with the excavation for the Panama Canal which will total 230,000,000 cubic yards. Most of the deposit consists of two per cent ore, but the value of the ore increases with the depth. Borings which in place have been carried down from 1,000 feet to 1,285 feet show that the underlying ore contains 3.17 per cent of copper.

Up to 1911 the deposit was owned by individuals and separate owners. Because a large part of it is exposed, and there is no surface soil to be stripped off, hundreds of open cuts have been made by miners who sought only high-grade ore. In fact, the whole surface of the mountain is honeycombed with such burrows. Some of them are 300 feet deep, but the total amount of copper excavated is comparatively insignificant, and nothing was done with the low-grade ore. Now the whole mountain has been taken in hand by an American company, which is prepared to excavate the entire deposit and recover the copper it contains by means of the electrolytic method. Work is well under way on a plant which will handle ten thousand tons or more per day.

Electricity will be furnished from a 40,000-kilowatt steam power house at Tocopilla (the man who is not familiar with South American geography will find this port on the map about twenty-two degrees south of the Equator) The power plant will have four turbo-generators of 10,000 kilowatts each. The fuel used in the plant may be either coal or oil, but it is planned to use oil, shipped from the California oil fields The transmission line running from the power plant to the electrolytic plant will be eighty-six miles in length and will be of sufficient capacity to deliver 21,000 kilowatts at the mine This will provide for treating ten thousand tons per day. The current will be transmitted at a voltage of 110,000, and the line will be strung on steel towers, spaced eight to the mile When the capacity of the treatment plant has been increased to double that amount a second transmission line will be erected Although there is some water-power available in the vicinity of the mine, it was decided to build the steam power plant on the coast in order to save time. Later on hydro-electric power will also be used

The ore will be mined with steam shovels from the Panama Canal The method of extracting the copper will be to crush the ore and place it in large concrete tanks. Here it will be treated with a copper sulphate solution, consisting of eight per cent sulphuric acid and one and one half per cent copper After soaking here for forty-eight hours the solution will be passed through the electrolytic tanks where the copper will be deposited. The sulphuric acid left in the tank after the copper has been extracted will be used for the treatment of the crushed ore. After the first treatment with sulphuric acid, no more acid will have to be introduced into the operation as enough will be obtained from the electrolytic tank, which will extract the sulphate in the ore. Experiments with this method of recovery show that ninety per cent of the copper in the ore can be extracted. Hence, it is expected that the ten thousand ton plant now being built will produce 120,000,000 pounds of copper per year. The mill is about three miles from the mine; and a plant railroad is being built which will be about twelve miles long The Chuquicamata mine is reached by a branch line from the Antofagasta and Bolivia Railroad, and is a hundred and fifty miles by rail from Antofagasta

Over fifteen hundred men are at work on the plant.

To accommodate the workmen at Chuquicamata the company is building a city which will contain among other buildings a soldiers' barracks, two public schools, a court house and telegraph and postal building, a theater, a hospital, a public quarantine, a Protestant church and a Catholic church, a music hall for workmen, and a public library The city will consist of two sections, one for foreigners and the other for natives It will probably be the finest industrial town in South America. Work on the plant, the power plant, and the workmen's villages are proceeding rapidly, and it is expected that copper will be produced within a year's time.

Air Pressures in Playing Wind Instruments

IN an interesting article in the *Philosophical Magazine*, Mr. Foord refers to Dr Stone's table of wind pressures required to play various notes of the scale on various wind instruments. The table indicates that as the notes rise higher in the scale the air pressure necessary to produce them increases with most wind instruments, although not with all In the clarinet, for example, the pressure decreases from the low notes to the high ones, varying from 15 inches of water to 8 inches. Mr. Foord repeated these experiments on the clarinet and saxophone, playing the whole range of notes first loudly and then softly For the clarinet it is found that the pressures fall as the notes rise, agreeing with Dr Stone's table, although the inverse law holds good for the oboe, bassoon, horn, cornet, trumpet, euphonium, and bombardon.

With the saxophone it is found that the pressures corresponding to notes at the beginning and end of the register are equal, the pressure rising to a maximum at the note D about half-way through the scale

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

Tolls Question in the House of Representatives

ALTHOUGH on grounds of decency and dignity there was much to deplore in the debate which preceded the passage of the Tolls Repeal Bill in the House, it is perhaps as well that its opponents should have given loose rein to the prejudices and animosities which characterized their speeches These gentlemen have spoken and the country has listened with close attention, with much enlightenment, and incidentally with no little amazement

The country has a right to expect of its representatives that whenever a subject of grave international importance, such as this question of tolls, comes up for debate, it shall be considered strictly upon its merits, and that the discussion shall be free from the least taint of mere party politics and all the insincerity, byplay, and subterfuge which the "political game" implies Above all, a debate of this kind should never be vulgarized by the interjection of personalities

Say what he will, the most bitter opponent of repeal must admit that this country is on trial before the whole world in the matter of its good faith and the sanctity of its treaty obligations There is no getting away from this fact; for the President himself, in a joint session of the two Houses, has so stated the situation, telling Congress in simple words of unmistakable meaning, that the honor of the country was at stake

Surely, anyone with the most elementary sense of ethics, or even of the common proprieties, must have felt that this was an occasion for cautious and dignified debate; and to the credit of many of the opponents of the bill, it can be said that their speeches were delivered in this spirit.

But, although many of the representatives spoke and voted against repeal under a mistaken but sincere misapprehension of the treaty, some of the opposition were manifestly swayed by other motives than a desire to get at the truth. Among these were subsidy seekers pure and simple; those who do not hesitate to stir up racial animosity; and not a few who did not disdain to descend to personal abuse of the President himself

As regards the last-named, it is sufficient to say that envy has ever been the parent of malice President Wilson is too firmly established in the confidence and respect of the country to be shaken by the angry ·battering of a few disappointed politicians

There is no doubt that the principal opposition to the bill comes from the coastwise shipping interests and from the politicians. Such opposition as has been developed among the public at large is the result of an active campaign, in which the arguments have been of the most specious character, and have consisted largely in an appeal to racial prejudice We had hoped that this sort of tactics belonged to an earlier and cruder day No one seriously believes that the President has taken his firm stand in favor of fulfilling treaty obligations on any other ground than that of national honor. To suggest that he is acting under pressure from any foreign power, and that he has made a "deal," in which our own treaty rights have been used to buy off foreign interference in Mexico or elsewhere, is to do violence to the very qualities which have won for our President so strong a hold upon the confidence and high regard of the country.

The Tolls Bill has gone to the Senate strengthened by the prestige of its passage through the House. The questions involved are: First, can we as a nation which boasts of its square dealing afford to repudiate a clearly-stated treaty obligation? Second, is there any good reason why a large portion of the revenues of the Canal, built, as it has been, by all the people of the country, should be diverted to that exceedingly small minority of the people who own and run our coastwise shipping? We believe that the patriotism and clear thinking which carried the bill through the House will prevail in the Senate also.

The North River Bridge Problem

PROMINENT among the great engineering questions which perennially thrust their way into public notice through the medium of the public press, is that of the construction of a bridge across the North River. So many have been the ways and means which have been proposed for putting through this work, that the public will welcome in this issue the clear and comprehensive letter from Gustav Lindenthal, who a quarter of a century ago made the first definite proposal and working plans for a bridge across the North River. As Bridge Commissioner under the Mayor Low administration, the writer of this letter had every opportunity to become acquainted with the ins and outs of the construction and operation of great public utilities, and notably of the great bridges which have been built across the East River.

Every one admits that the time is ripe for the provision of larger and more rapid facilities for intercommunication between New York and Jersey City; and the two questions upon which there may be division of opinion are first, as to whether this communication should be established by a single monumental bridge or by multitudinous tunnels; and second, as to whether the results can be best achieved by public money, that is by the cities and States concerned, or by private capital.

Judged on the score of the capacity afforded for a certain cost, there can be no question that a bridge is to be preferred to tunnels. A bridge such as that illustrated in this issue, costing $76,000,000, would have the same capacity as nine pairs of tunnels, costing $180,000,000. Next to the railroad traffic, the automobile traffic will be the largest; and it is certain that the multitudinous automobiles and motor trucks would travel with more safety and convenience by way of a bridge than through tunnels that must be three miles in length if the grades are to be kept down to a reasonable limit There would be serious fire risk in sending a heavy automobile traffic through a three-mile tunnel, and the problem of getting rid of the noisome gases in tunnels of such a length is a very serious one indeed Indeed, the difficulty of ventilating tunnels of that length that were carrying a heavy automobile and motor truck traffic would seem to be almost insuperable.

To insure its success, any plan for connecting Manhattan with New Jersey should include the co-operation of the railroads, at least so far as the handling and distribution of freight is concerned. The present method of distribution by car float and trucking, not only encumbers the river and the Manhattan piers and marginal streets, but it is antiquated and altogether behind the best modern practice. The city has under advisement plans for a great marginal elevated freight railroad and storage warehouses, which would be rendered doubly efficient if the freight trains were brought in to Manhattan over a bridge to a connection with the marginal elevated tracks.

As to the question whether the bridge should be built with public or private funds, we think there can be no doubt that the latter plan, as outlined in Mr Lindenthal's letter, would be the more satisfactory He tells us that every one of the four existing East River bridges cost from 80 to 120 per cent more than the original estimate at the time the bridges were authorized, and this is only in keeping with the sad experience which New York city and State have had with regard to other important engineering works that have been built with public funds. The Catskill Water Supply, originally estimated to cost $160,000,000, will probably total nearer $200,000,000 by the time it is completed; and the Erie Canal, estimated to cost $100,000,000, promises to cost nearly $150,000,000

If the present grossly unfair treatment of the railroads shall come to an end, that is to say, if they are once more permitted to operate according to true economic laws and, therefore, should feel justified in facing large expenditures in improvement of their systems, they will probably find the proposed railway connection with Manhattan an attractive proposition; and if the two States, New York and New Jersey, should co-operate, we understand that there would be no difficulty whatever in securing from private sources the $76,000,000 of capital needed to build the bridge.

Dr. Zimmerman's Aerodynamic Studies

A NOVEL and most important line of work in advancing aeroplane design has been inaugurated by the section for scientific aviation of the *Berliner Verein für Luftschiffahrt*. The task was to determine and correctly measure vital constants of a Grade monoplane, such as weight, center of gravity, moments of inertia, and most important, the several axes of inertia oscillations. Dr. Zimmerman, who worked out the theory of these investigations, was in charge of the work, which with the rather primitive accommodations at his command took no less than twelve days. It was found that to take these important measurements of any finished machine speedily and economically, an entirely new accessory to the flying machine is needed; a large dome-shaped building, with facilities for suspending the aeroplane in any desired fashion, so that it is free to oscillate only about the axis to be investigated, with windlasses, and also swinging galleries, by which any portion of the machine can be approached without disturbing the rest.

These constants are at present only partly known. A correct understanding of the several axes of inertia oscillations (the various axes, fixed by the arrangement of weight, about which a machine begins to rock if its equilibrium is disturbed in different ways), will simplify the all important stability problem, which has so far been dealt with only by cut and try methods, and which in the aeroplane is a matter more of dynamics than of statics. It will give us safer and more useful machines.

Such an advance is more beneficial than a new record made by a flying virtuoso, who cannot impart his personal, almost subconscious art to others.

The Composition of Air and Rain-water in the Antarctic

ONE of the most interesting undertakings of Dr. Charcot's expedition to the Antarctic in 1909 and 1910 was the collection by Ensign R. E. Godfroy of the French navy, in accordance with the instructions of A. Müntz, of a great number of samples of air and meteoric water (rain and melted snow), which have since been analyzed in Paris. An elaborate report on the analyses has been published by Messrs. Müntz and Lainé in the *Annales de l'Institut National Agronomique*. In order to determine the amount of nitric acid in the atmospheric precipitations of the Antarctic, samples of meteoric water, as collected, were dosed with a small quantity of potash, concentrated by evaporation over a flame, mixed with alcohol, and hermetically sealed. This substance is supposed to be formed by the electrical discharges of thunderstorms; a belief supported by the fact of its relative abundance in tropical regions, and its almost complete absence at great altitudes, where thunderstorms rarely occur. The samples brought back by the Charcot expedition show that it is approximately as abundant in the Antarctic as in Europe, despite the rarity of thunderstorms in high southern latitudes. It may, however, be produced elsewhere and carried thither by the winds. Other samples, collected by a different method for testing the percentage of ammonia, show that the latter substance occurs in about the same quantities in the Antarctic as in middle latitudes Samples of air were collected for the purpose of testing the amount of carbon dioxide. In the atmosphere of the world as a whole this gas has heretofore been stated to form a little less than 3 parts in 10,000 by volume. Determinations by Müntz and Aubin at a number of places in the northern hemisphere give a mean of 2.82, while at Cape Horn they found only 2.56. The mean of all the samples collected by the Charcot expedition shows the strikingly low value of 2.05.

The Monthly Weather Review

PERSONS interested in meteorology will be glad to see in the January, 1914, number of the *Monthly Weather Review* a return to something like the scope and character which made this journal one of the most useful periodical publications of the Government prior to July, 1909. The status of meteorology in the United States is peculiar in the fact that all but a very small percentage of its devotees are connected with the official Weather Bureau, either as paid employees or as volunteer observers, and are therefore entitled to be supplied with professional literature at Government expense. For this reason it seems impossible to maintain an independent meteorological journal in this country. The admirable *American Meteorological Journal*, published from 1884 to 1896, was not only a labor of love, but a source of heavy expense to its editors. After it ceased publication the official *Monthly Weather Review* gradually broadened in scope and became known throughout the world as the mouthpiece of American meteorology. In 1907 the Weather Bureau established a more strictly technical and decidedly less readable publication known as the *Bulletin of the Mount Weather Observatory*, and in 1909 the *Monthly Weather Review* became mainly a bulky collection of climatic statistics. Its literary features, though not entirely eliminated, were mostly devoted to questions of local climatology. In short, from July, 1909, to the beginning of the present year, the United States possessed no journal of general meteorology, such as has now, very fortunately, been re-established.

Engineering

The Electrification of Chicago Railway Terminals.—An elaborate report on the question of smoke abatement and the electrification of the railway terminals will be presented in a few months' time by a committee of the Chicago Association of Commerce. The work of the committee was commenced in 1911, and in the interim it has made a most extensive study of 4,500 miles of railway track, including nearly 100 railway yards.

Excellent Torpedo Record.—The United States cruiser "California" recently established a new record for torpedo firing during battle practice off the coast of California. The firing took place at a range of 3,000 yards when the cruiser was steaming at 10 knots. The first five shots were bull's eyes, the sixth was a miss, and the seventh torpedo stuck in the tube, and according to the rules was counted as a shot.

Another Large Motor Ship.—There was launched by Messrs. Harland & Wolff on March 12th a large motor ship, the "Falstria," for the East Asiatic Company, who are the owners of the "Selandia," and sister ship. The "Falstria" is 381 feet long, 50 feet broad and has a gross tonnage of 4,500. The main engines will consist of a pair of Burmeister & Wain four-stroke, six-cylinder Diesel engines, with two auxiliary Diesel engines for the air compressors and dynamos.

An Oil-Burner Record.—The freighter "Santa Cruz" arrived last month at San Francisco with a new record for the passage by way of the Straits of Magellan. From the time the vessel left Sandy Hook till she slowed down off Los Angeles harbor, the engines were run full speed without a stop, and the distance of about 13,000 miles was made in 47 days and 4 hours. The "Santa Cruz" is an oil burner, and therefore did not need to put in at any port for fuel.

The Soo and the Suez Canals Compared.—William C. Redfield, Secretary of Commerce, in a recent address drew attention to the fact that the number of ships passing through the river and canal connecting Lake Huron and Lake Superior amounted last year to nearly three times the number that passed through the Suez Canal. To be exact, 14,916 vessels of 30,974,123 tons passed through the Great Lakes Canal, while 5,300 vessels of 20,275,133 tons passed through the Suez Canal.

The Situation at Cucuracha Slide.—The last number of the *Canal Record* states that approximately 1,000,000 cubic yards of material has been dredged from the toe of Cucuracha slide. The dredges began operation there on October 26th, 1913. On March 4th the channel at the base of the slide had a minimum width of 190 feet and a minimum draft of 20 feet at the level of Gatun Lake. The removal of this material has caused a marked lowering of the masses of material in the upper reaches of the slide

A Concrete Hardening Material.—Mention is made by the *Engineer* of a concrete hardening material containing 95 per cent iron dust or iron flour, which is mixed with cement for finishing the surface of concrete floors. From 15 to 25 pounds of the material is mixed with 100 pounds of the cement while dry, and one part of this mixture to two parts of sand is used for the top coat, which varies from one half inch to one inch in thickness. It is said to make a hard and durable floor. It is serviceable also in making new concrete adhere to old concrete in repair work.

Canal Machinery Should Be Sold.—The suggestion has frequently been made that the canal excavating machinery might be used to good effect in levee work on the lower Mississippi, or that some of the machinery might be used to build the Alaska railroad, or to do general river and harbor work in the United States. Col. Goethals recently told the Senate Commerce Committee that it would be more economical to purchase new machinery outright for the Mississippi improvements than to remove and repair the canal machinery. The only part that might be utilized would be some of the dredges, and these, he thought, would be of doubtful utility. He recommended that cars, dredges, engines and all other machinery be sold to South American interests which wish to use them in railroad building.

United States Collier "Jupiter" Makes Over 15 Knots.—The Navy Department is much gratified with the performance of the large collier "Jupiter," in which is being tried out a system of electrical speed reduction. The motive power consists of a turbine-drive, direct-connected to a generator, current from which drives the propeller shaft motors. The contract calls for the maintenance of a speed of 14 knots for 48 hours continuous steaming. On the recent official trial the collier maintained 15.1 knots for 48 hours, an excellent performance, which compares favorably with that of the sister ships "Neptune" and "Cyclops." The former, fitted with Westinghouse reduction gear, has maintained 14.96 knots for 48 hours, and the "Cyclops," fitted with reciprocating engines, has maintained 14.61 knots for the same length of time.

Science

The Fourth International Botanical Congress will be held in London, May 22nd–29th, 1915.

Paint From Beans.—From Manchuria comes the invention of a new paint that is both waterproof and fireproof in addition to being cheap and durable. "Solite" is the name of this new product, and three months after its introduction it found a ready market in Shanghai, Harbin and Tientsin. It is reported that the Japanese navy is testing it with a view to adoption. "Solite" is made from bean oil which is produced in tremendous quantities in Manchuria.

An 1,800 Years Old Egg.—An egg which cannot be said to be fresh is one which dates from 1,800 years back. It was found during recent excavations made at Nikopolis, in the tomb of an 11 months old child, Sextius Rufus. Already more than 80 tombs have been explored by the archæological service in this ancient city, which was built to commemorate the battle of Actium. Among the finds are a quantity of gold jewels, also pottery and lamps ornamented with elegant figures in relief.

The Kritzinger Comet.—A cablegram received at the Harvard Observatory from Kiel announces the discovery of a comet by Dr. Kritzinger of Bothkamp, in the following position:

March 29.6171 G.M.T.
R.A. 16h. 11m. 39.2s.
Dec. —9° 30′ 45″

The comet had a daily motion of +3m. 08s. in R.A., and +32′ in Dec., and was visible in a small telescope.

Further Exploration of the Abor Country.—The northeast frontier of India has become the theater of active and much-needed exploration by British officials, beginning with the operations of the punitive expedition sent against the Abors after the murder of Messrs. Williamson and Gregorson in 1911. During the past winter, a small party was engaged in exploring and surveying the country of the Akas, the most westerly of the Abor Mishmi group of tribes. This region had not been entered by a British party since 1884.

Shorthand Taught by Moving-picture Slides.—The value of illustrated moving-picture slides for teaching shorthand is being successfully demonstrated by a school of Newark. The principal, A. J. Harding, who originated and developed the scheme, has been working on it for the past year and recently began its use in the shorthand department. The moving-picture idea is not only pleasing and agreeable, but is an incentive to the student to accomplish more, for the reason that he is appealed to from a more interesting point of view.

Tomato Seeds for Fodder.—The Chamber of French Commerce at Milan announces successful attempts to produce a valuable cattle-fodder from the tomato seeds which are a by-product of the canneries. The seeds are desiccated in drying-furnaces and then sifted to separate them from the woody fiber of the debris. They are then crushed by heated mill-stones and the oil which they contain in considerable quantities is separated by a hydraulic press. The residue is pressed into loaves each about two kilogrammes in weight. According to tests at the Agricultural Station at Portici, they contain an abundance of proteids and carbohydrates.

Explorations in Northeastern Siberia, on an extensive scale, have been undertaken by Iden Zeller, especially for the purpose of making ethnological collections for the museums of Hamburg and Leipsic. Starting from Yakutsk with a column of natives, the explorer expects to sledge first to the Kolyma River, where he will spend the latter part of this year. After an excursion all the way to Cape Deshnev, he will travel west to the Yana River, and sledge over the ice to the New Siberian Islands, where he has been commissioned by the Russian government to erect a bronze tablet in memory of the late Baron Toll. Later he will explore along the lower Lena and then westward by way of the Taimyr peninsula to the Yenisei and the Ob. He hopes to complete this remarkable journey late in the summer of 1916.

The Abnormal Propagation of Sound Waves in the Atmosphere is discussed in a recent paper published in Tokyo by S. Fujiwhara (who in other memoirs has spelled his name "Fujihara" and "Fujiwara"). The existence of regions of audibility lying farther from a source of sound than regions in which the sound was inaudible ("zones of silence") has been reported in connection with certain great explosions by G. von dem Borne and A. de Quervain, and made especially prominent by Alfred Wegener, who sees in this phenomenon the result of total reflection of sound from an upper atmospheric stratum of great tenuity. Mr. Fujiwhara has collected numerous reports of the audibility of great explosive volcanic eruptions in Japan. He finds that the existence of a silent region is a usual phenomenon, and that the region of audibility always lies in a special direction from the source of the sound; viz., the same direction as the axis of the region in which sand and ashes fall from the volcano. The principal factor in the anomalous propagation of the sound is the wind, and the phenomenon is found to be closely related to the prevailing type of weather.

Aeronautics

The New Noiseless Zeppelins.—The new army Zeppelin V cruised over Berlin recently with hardly any noise whatever In the past Zeppelins have been conspicuous by reason of their noise. Their approach was heralded long before they appeared, by buzzing motors. The latest Zeppelin, the Z8, flew over Santis Mountain in the Canton of Appenzell on April 1st, and in so doing created a new height record for dirigibles of 10,000 feet.

Entries for the Gordon-Bennett Aviation Cup.—According to *Flight* the following entries have been made to the Royal Aero Club: Messrs. A V Roe & Co, Ltd., Manchester; Sopwith Aviation Company, Ltd., Kingston-on-Thames, British and Colonial Aeroplane Company, Ltd., Bristol; Cedric Lee Company, Shoreham (two machines); Messrs. Vickers, Ltd, Erith and London. The race will be held in France in September or October next, and the Royal Aero Club will select from the foregoing entries three competitors to represent the British Empire.

An Aerodynamic Laboratory for Massachusetts Institute of Technology.—The first structure that the Massachusetts Institute of Technology has caused to be erected for its own uses on its site in Cambridge is the new aerodynamic laboratory. The building is finished and the apparatus is in process of installation. This, together with the fact that Technology has already instituted courses in the study of this science, makes it the first college in the land to be fitted to prepare students for what must in the future be an exceedingly important line of development. The portion of the equipment that is first to be installed, in fact, is nearly ready for use, is the four-foot wind tunnel with its accompanying blower. This is of the pattern now in use at the National Physical Station at Teddington, England.

A Giant Hydro-aeroplane.—The Jeanson-Collieux hydro-aeroplane is one of the largest machines ever built, rivaling indeed even the machine of Sikorsky. It is stated in the French press that the machine flew several miles recently above the Seine River at Priel. The machine is carried by a single boat having a single hydroplane step. The boat is 28.5 feet long by 8.5 feet beam. The aeroplane portion consists of two sets of biplane surfaces arranged in tandem The span is 27 meters (88½ feet) and the total lifting surface 145 square meters (1,560¾ square feet). Within the boat body are two 200 horse-power motors connected by sprocket and chain with a single air propeller 5 meters in diameter. The total weight of the machine with its pilot, assistant pilot, two mechanicians and fuel and oil for a 15-hour flight (1,600 kilometers—994 miles) is 4,700 kilogrammes (10,360 pounds).

The Race to Bermuda.—An aeroplane race from New York to Bermuda, over a flying course of 700 miles, is being organized for the coming summer The machines are to leave here in the last week of June or the first week in July. Prize money to the amount of $25,000 will be awarded upon their arrival in Hamilton Harbor, Bermuda. If the race actually takes place it will be extremely instructive because it will shed much light on the possibility of crossing the Atlantic in machines of the present day, for the oversea flying course will be practically one third of the distance which machines entering the transatlantic race would be expected to cover. For a long stretch the aviators will have to fly without any land in sight, relying only upon the compass. The aeroplanes entering for the race will be required to carry wireless outfits capable of transmitting signals to a distance of 75 miles.

France as an Aeroplane Power—A serious controversy has arisen in France, which is the direct outcome of the great national aeroplane subscription inaugurated two years ago, and as a result of which 208 aeroplanes were presented to the French army Of these, all but 33 were in active use at the end of last October. These aeroplanes were an addition to the direct orders placed by the army. It is alleged that the aeroplanes bought through the national subscription were not new, and that the orders for new machines fell short by 200 of the number voted. The National Committee, of course, repudiates the charges indignantly, but the French newspapers seem to think it only too probable that certain manufacturers did, in fact, seize the opportunity to dispose of machines not of the most recent and improved type. The investigation started by the National Committee at least served the purpose of calling attention to France's aeroplane strength. In the first year 320 aeroplanes were delivered at the depot at Chalais-Moudon, while the definite orders placed for 1913 amount to a total of 431, of which 286 had been delivered at the end of October last and the balance by now. As a result, 751 aeroplanes have been acquired by the aeronautical establishment of the French army during the past two years and close upon 1,000 machines since the beginning of 1911 Blériot alone has built 181 military machines and Henry Farman 105. No wonder that France has a real aeroplane industry!

The Plumbing of the Human Body

The Surgeon as a Sanitary Engineer

IN the history of every science we can point to certain landmarks, milestones as it were in the road of progress, which stand out prominently from among the general level of gradual advances. Such epochs mark the ushering in of a new era, the opening out of a new horizon

Has such a point been reached in contemporary medicine? As much has been hinted by some members of the medical profession, and only the future can show to what extent their anticipations will prove warranted by subsequent developments

If we look back to the early days of the history of medicine we find a very crude hypothesis, the humoral theory, forming the basis of medical teaching and practice. According to this, the cause of disease lies in the human economy, *in which the balance between the four* "humors" has in some way become disturbed. Remnants of this speculation are still found in our everyday language, in such expressions as "melancholic" or "choleric" temperament—since the humors (Greek chole, bile) were supposed to determine a man's temperament.

Fig. 5.—Elbow joint of a coal trimmer.

Since the days of Pasteur we have become accustomed to seek an external cause for many diseases, which owe their origin to bacterial infection

But this is only a partial solution of the problems presented by disease, for it is well known that we all daily take into our bodies countless microbes without suffering any observable ill effects.

In fact, microbes have little or no terror for the man "in perfect condition"—before they can gain a footing the ground must have been in some way prepared for them, there must be "predisposing" circumstances. This, of course, has long been well understood, but it would seem that one very important predisposing factor has not been fully appreciated or traced to its ultimate source. True, it has always been realized that disturbances in our alimentary tract were responsible for many more or less grave consequences and predispositions for disease True, also, that Prof. Metchnikoff in particular taught very emphatically the deep significance of fermentative changes going on in the intestine, and their probable relation to the premature "ageing" of the individual.

But if the views now put forward are substantiated by further evidence, it would seem that one of the dominating factors producing many of the disorders of our alimentary tract, with the far-reaching consequences in their trail, had not hitherto been properly appreciated. This factor is in the first instance purely mechanical, and relates to the manner in which the intestine is held in place in the human body.

It must be remembered that the upright posture of man is presumably a somewhat late acquisition in the progress of his evolution. There are indications that various structures of the body, and in particular the abdominal viscera, have not yet fully become adapted to the comparatively new conditions of erect posture. How far unusual mechanical stresses may go in modifying anatomical structures will be seen from one of the accompanying illustrations, which shows the spinal column of a brewer's drayman, twisted all out of shape to meet the "new conditions" of the stresses produced in the habitual carrying of a cask on the right shoulder. Another engraving shows the elbow joint of a coal trimmer. It has become much strengthened by buttresses of bone which increase the area of the articular surfaces and render the fit more accurate.

These advantages have been gained at the expense of an abnormally limited range of flexure, the photograph showing the arm in its limiting position.

These are examples of some of the changes produced in the human anatomy by nature's efforts to meet new and unusual conditions As is clear from the illustrations given, the result is far from being wholly happy—an advantage is gained at the expense of some more or less undesirable deformity. And what has this to do with disorders of the alimentary tract? The connection is obvious enough once it has been made clear, as it has been by the labors of Sir Arbuthnot Lane. Nature, in its effort to afford adequate support to an intestine deprived of its original resting base, the abdominal wall, produces here and there special supporting bands—crystallizations as it were of lines of force, lines of tension—to suspend certain loops of the canal. If the matter stopped there, all might be well. But under undue stress, caused by injudicious attire or mode of living, these bands gradually outgrow their proper limits, and instead of being merely supporting members, and thus useful, they become distorting members, causing the intestine to become kinked, and rendering the passage of material through it more and more difficult. Thus, according to Lane, arises the condition technically known as intestinal stasis. The plumbing of the human body is out of order and stagnant. Poisons, toxic products, which ought to be discharged, are retained in the body and produce effects manifesting themselves in a great variety of ways.

As regards the harmful influence thus exerted, Sir Arbuthnot Lane, in an address delivered at the North East London Post-Graduate College, says:

"Perhaps the best scientific confirmatory evidence I can put forward of the harmful effect of defective drainage, both of the body as a whole and of the several tissues which constitute it, has been afforded recently by the remarkable experiments of Carrel in the growth of living tissue, in which he has shown that tissues are immortal, and grow to the greatest advantage if the drainage of their toxic products is carried out effectually."

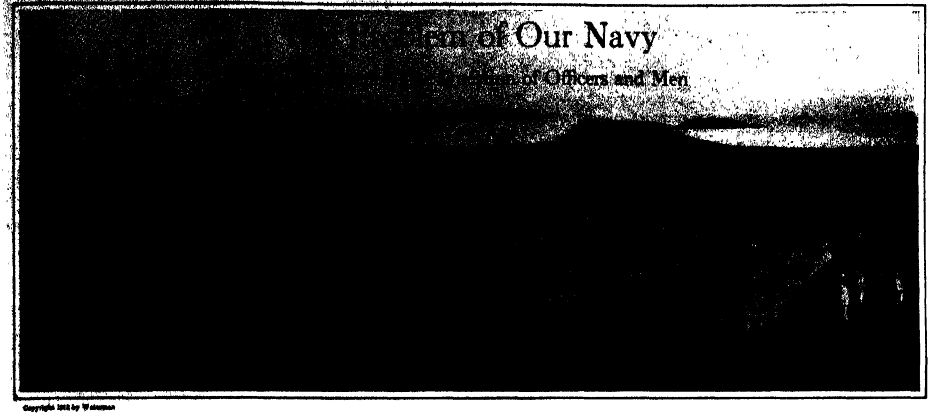
The field thus opened up by Lane has been entered by a number of prominent members of his profession, whose findings seem to substantiate his views. Says Dr. William Seaman Bainbridge in the *Boston Medical and Surgical Journal:*

"It seems to me that he (Sir Arbuthnot Lane) makes out a very good case for his mechanical or evolutionary theory of the origin of all the adventitious structures which, in his opinion, play so important a part in the production of chronic intestinal stasis. It may be said, however, that much work needs yet to be done before any theory can be firmly established. We are only beginning to explore the field which he has opened to us. The establishment of the existence of these various structures takes us a long way. We have yet to determine more about their origin, and to follow the leads which he has given us with reference to the far-reaching effects of the conditions brought about by the development of these structures. The field, it seems to me, is one of the most alluring and promising which modern medicine and surgery present. It is certainly rich in promise for the many who, otherwise, would be doomed to more or less complete chronic invalidism."

In the diagnosis of stasis, X-rays are most valuable in disclosing kinks in the intestine. The treatment may consist in medication, in "ironing out" kinks by judicious exercise and wearing of suitable belts, or, in more pronounced cases, surgical interference may become desirable. This may consist merely in the cutting of some of the adherent bands, or in extreme cases, the greater part of the large intestine (colon) may be sidetracked, i. e., short-circuited or removed. The colon appears often to be a rather unnecessary and in some cases even a harmful organ, which can well be spared when the need arises.

em of Our Navy

of Officers and Men



Copyright 1912 by Waterman

IF we were asked to select the one element of supreme importance among the many which go to make up naval efficiency, we should unhesitatingly name the personnel—the officers and men. In saying this, we are mindful of the fact that in previous articles of this series we have shown that the instruments of war will have a much greater influence in determining the issue of naval battles of the future than they had in the days of sail power and the smoothbore. The highly technical and scientific character of war material—ships, guns, instruments of precision, etc.—undoubtedly has exercised a general leveling effect, and has tended to give *matériel* a greater relative importance as compared with personnel than obtained in an earlier age. While that is undoubtedly true, and no amount of dash and courage can counterbalance a great superiority of the enemy in *matériel*, the fact remains that, when the contending fleets are approximately equal in strength, the issue of the fight will be determined by the judgment and skill of the officers and the discipline and courage of the enlisted men. For proof of this we do not have to go further back than the Russo-Japanese war and the often-quoted battle of Tsushima. In that great fight the fleets were fairly well matched; indeed, if there was any advantage, it lay with the Russian fleet, the leading ships of which represented the most advanced practice in naval construction. Moreover, there was a decided superiority in the number of armor-piercing guns carried by the Russians.

But on the Japanese side the ships were manned by highly trained and experienced officers and thoroughly disciplined crews, whereas the personnel in the Russian fleet consisted of officers of little experience in naval maneuvers and the enlisted force was largely made up of absolutely untrained crews, many of whom were making their first voyage in a warship. The result was inevitable, and the really excellent first fighting line of the Russians, poorly maneuvered and unable to either seriously hurt the enemy or to present that defense which a well-directed fire always offers, was completely overwhelmed in one of the briefest and most sweeping victories recorded in all the history of naval warfare.

The preceding articles of the present series on our Navy have been so largely critical that it is with relief that we turn to a phase of the question in which we can speak of the Navy in terms of unqualified commendation. It is our belief that the personnel of the United States Navy, as regards both the officers and the men, is the most efficient to be found in any of the navies of the world. As a people, from the very beginning of our history, we have shown a peculiar aptitude for the sea; and this is true both of the Navy and of the merchant marine. Our clipper ships of the middle period of the nineteenth century were the fastest and most ably handled of any that have ever sailed the seven seas; and in the war of 1812 it was proved over and over again, in many a hard-fought duel, that, under equal conditions, ship for ship and crew for crew, we were more than a match for the enemy. *Whenever the Congress has given our Navy a chance and treated it with reasonable liberality in the provision of ships, officers and men, the Navy has responded most nobly to the call, and in all the history of the republic there are no pages which are read with more justifiable pride than those which tell of the exploits of our individual ships upon the high seas.*

One does not need to have a very intimate knowledge of battleships, torpedo boats, submarines, and of the complicated duties involved in the command of a warship, and in the maneuvering of squadrons and fleets upon the high seas, to realize that the successful discharge of the duties of a naval officer imposes a strain upon his physical and mental powers, so great that it can be successfully endured only by men of exceptional physique, training and ability. From the time of his graduation from Annapolis, the naval officer, whether as ensign, lieutenant, commander, captain or rear admiral, has imposed upon him duties which for their successful fulfillment will make heavy demands upon his physical and mental equipment. His rise in the service will depend upon his ability and zeal, and upon the nature of the service regulations which are made for passing him up from grade to grade as he rises in rank. His zeal and abilities are personal to himself; but the service regulations, so far as they govern his rise, are arbitrary. As matters now stand, the regulations for the promotion of officers are extremely faulty; for they tend to keep him so long in the lower grades that by the time he is promoted to the command of squadrons and fleets, he is long past his prime, and therefore is not able to do justice to himself or to the service under the very exacting duties and graver responsibilities that have come upon him.

The admiral who leads into battle a fighting line of twenty dreadnoughts is responsible for 20,000 men and $200,000,000 worth of the nation's property, which, through his momentary indecision or error, may be destroyed in an hour's time and would take many long years to replace. A rear-admiral is responsible for $50,000,000 worth of property, and each captain for $10,000,000. Weighed in the monetary scale, the responsibility of these officers is enormous The financial loss in the event of defeat, however, is insignificant compared with the fact that the annihilation of that battleship line would mean for the United States the complete collapse of our foreign policies, the loss of our insular possessions and a blow to our lately-acquired prestige as a leading world power, from which it would take us many a long decade to recover. Evidently the men who hold command rank, all through the grades from lieutenant-commander to admiral, should represent the very cream and flower of the service. They should leave each grade thoroughly equipped with the knowledge and facility which can be gained only by serving the term of years incidental to the various grades, as they pass through them. Furthermore, the naval officer should be possessed of that almost instinctive quickness of perception and action, which can result only from years of experience in that particular grade in which he is serving when the critical hour of battle arrives.

Are the conditions which govern promotion among the officers such as will secure the above results?

They are not; for unfortunately the present laws as determined by Congress are not such as to bring the best of our officers to the upper grades sufficiently early in their lives to give them that combination of mental and physical vigor and ripe experience which is necessary to make them fully efficient.

The total number of line officers and the number in each grade are determined each year by Congress; and there is no prerogative of Congress which it guards so jealously and with regard to which it is so sensitive as that of fixing the number of our land and naval forces. Thus, for the present year Congress has determined that there shall be 18 rear-admirals, 70 captains, 112 commanders, 170 lieutenant-commanders, 800 lieutenants, and 350 junior lieutenants and ensigns Entrance to the Navy is by way of the naval academy at Annapolis, and entrance to Annapolis is by appointment under a law which grants to each Congressman and each Senator the privilege of appointing two young men to the Academy. Also forty are appointed each year by the President.

Now, under this arrangement the Naval Academy is sending into the service from 150 to 160 graduates per year That is the supply; and every one of these young men, as he leaves the Academy, should have a reasonable expectation that he will rise steadily by merit and promotion from grade to grade, until he reaches command and flag rank, that is to say, the rank respectively of lieutenant-commander and admiral.

It is evident that, since Congress limits, each year, the number of officers in each grade, promotion from the lower ranks can proceed only as fast as vacancies occur. These vacancies are due to retirement on account of age (62 years) or to death, disablement, resignation, dismissal, and other causes The total vacancies from all causes amount to not over 50 per year. Hence, we have a situation in which line officers are entering the service at the bottom at the rate of 150 per year, and leaving it at the top at the rate of 50 per year, with the result that there is an ever-increasing congestion in the lower grades

Now the mischief of all this is that, unless the system be radically changed, our ensigns will be about forty years old before they are promoted to be lieutenants, and they will be about fifty years old before they reach the rank of lieutenant-commander, fifty-six years old when they become commanders, and well on the way to the Biblical "three-score years and ten" before they can captain a battleship. From this situation results the serious evil that, when the officers reach the ranks of captain and rear-admiral and are entitled to the command of battleships and squadrons, they have long passed that age in which they would have been most fit, both physically and mentally, to perform the difficult duties pertaining to these commands.

This congestion can be met· First, by applying the principle of the survival of the fittest, and selecting every year the best of the officers in each grade for promotion to fill the vacancies in the grades above; second, by removing those officers that are not selected to a reserve list. Those selected would constitute the "active" list, and from this list would be drawn the officers for the fleet in full commission. Those not selected would be transferred to a reserve list, from which would be drawn the officers for the ships in reserve and for duty on shore

But where shall we find a jury that will have a sufficiently intimate knowledge of the personality and record of the officers to enable it to select for promotion the most competent? Evidently the best judges are the officers themselves, who by close association and observation have an accurate knowledge of each others' fitness and ability. Hence, it is believed that the selection of the officers from each grade for promotion should be made by the vote of all the officers in the grade above. Thus the choice of the best among the lieutenant-commanders should be made by the commanders; of the best among the commanders by the captains.

Now it is evident that the number of officers and men authorised by Congress each year should be determined by the size of the fleet on the basis of the displacement of the ships. The Department should submit to Congress in December of each year a statement of the total displacement tonnage of all battleships and cruisers *of less than twenty-four years of age from the date* of their authorization, of all scouts, destroyers and submarines of less than twenty years from the date of authorization, and also of all ships of the above classes that will be commissioned during the fiscal year beginning July 1st following. The Department should submit, also, a statement of the number of officers and enlisted men that would be necessary to man the fleet, based on an estimate of three officers and seventy enlisted men for each thousand tons of displacement.

It has been suggested that the total number of officers so fixed, each year, shall be distributed as follows: One flag officer to four captains, to six commanders, to fifteen lieutenant-commanders, and to sixty-seven lieutenants, junior lieutenants, and ensigns.

The term of service in the various grades, supposing that the graduate from the Academy is about 21 years old, should be, reckoning from July 1st of the year of graduation: For promotion to junior lieutenant, 3 years; lieutenant, 6 years; lieutenant-commander, 12 years; commander, 18 years; captain, 23 years; rear-admiral, 31 years. This would bring the line officers to flag rank at about fifty years of age.

It is proposed that the flag officers (officers qualified to command squadrons, divisions, and fleets) shall be divided into the grades of admiral, vice-admiral, and rear-admiral, in the proportion of one admiral to two vice-admirals, and to ten rear-admirals.

The scheme for determining the number of officers and men in the fleet, as outlined above, is logical and thoroughly practical, and it should receive the legislative sanction of Congress. The increase in the personnel will bear an exact relation to the yearly increase in the size of the fleet as determined by Congress. Furthermore, it will insure that the officers as they rise from grade to grade, consist of the very pick of the service—a consideration the importance of which it is scarcely possible to overestimate.

Hitherto, there has been no such co-relation between the number of ships that were authorized and the number of officers and men provided to man them, and there has been, at times, a serious deficiency, rendering it impossible to man the ships of the active fleet with their full complements.

With regard to the enlisted force, it is gratifying to find that enlistment in the Navy was never so popular as it is to-day; and there is no doubt that this is in great measure due to the efforts of Mr. Daniels, the Secretary of the Navy, to render the Navy more attractive as a career to the young men of the country. This has been done by the inauguration of a system of instruction under the officers of the enlisted men aboard ship, for which a certain period is set apart each day. "By inspiring the confidence," says the Secretary, "that they will really have the double opportunity on shipboard of mastering a useful trade, and at the same time enlarging whatever academic educational advantages they have had, we will attract the very best of our youth to the Navy. And that is what we want, young men who will enlist in the Navy for the very love of the career, combined with whatever other practical advantages and opportunities there may be that will protect them in a financial way, in case of detachment from the service, by giving them the qualifications to take up a definite line of work

"The plan of instruction on board ship which has just become effective with a view to supply deficiencies in academic education and to providing systematic means by which all enlisted men and warrant officers who need it may receive assistance and instructions in technical branches to fit them for promotion in the Navy, or prepare them for civil trades at the end of their period of service afloat, is classified under two heads, academic and technical, or professional."

It goes without saying that the enlisted force of a navy should be citizens of the country under whose flag they serve, either native born or naturalized, and it is gratifying to learn from the last report of the Chief of the Bureau of Navigation, as shown by the accompanying table, that out of a total of 48,068 men in 1913, no less than 43,367 were native born, and 2,842 were naturalized citizens

We conclude this chapter with two instructive tables, one showing the composition of the personnel of three leading navies of the world, on April 1st, 1913, and the other the naval tonnage built and building in the year 1913-14.

CITIZENSHIP OF THE ENLISTED MEN OF THE U. S. NAVY.

	Native born.	Naturalized.	Aliens declared intentions	Aliens resident in United States.	Aliens non-resident in United States.	Natives of—				Total
						Porto Rico	Guam.	Samoa.	Philippines.	
Petty officers....	14,975	2,014	52	12	15	8	6	6	116	17,204
Other rates	28,392	828	62	106	265	38	71	81	1,021	30,864
Total	43,367	2,842	114	118	280	46	77	87	1,137	48,068

PERSONNEL OF THREE LEADING NAVIES.

	Germany	United States	Japan.
Total number of officers	6,353	2,966	5,246
Total number of enlisted men	60,920	47,496	42,043
Ratio of total officers to enlisted men	1 to 9	1 to 17	1 to 8
Ratio of line, engineer and warrant officers to enlisted men	1 to 11	1 to 20	1 to 9
Marine officers	170	316	None
Enlisted men (marines)	5,826	9,866	None
Total officers and enlisted men	73,269	60,617	47,289
Total number of flag officers allowed	40	18	70
Total captains and commanders allowed	351	182	292
Total other line and engineer officers	2,738	1,471	2,695
Total warrant officers	2,615	697	1,520

We draw attention in the table of personnel to the fact that for the number of enlisted men our Navy has about one half as many line officers and warrant officers as Germany and Japan. The importance of having a large reserve of officers to step into the places of those that are killed or disabled in the course of an action cannot be disputed.

NAVAL TONNAGE BUILT AND BUILDING 1913-14.
(JUNE 1ST, 1913.)

	Germany	United States.	Japan.
Naval appropriation	$111,288,618	$140,736,526	$70,302,662
Amount devoted to new construction	$52,179,113	$35,825,695	$24 144,446
Percentage devoted to new construction	47	25	34
Resultant new construction in tons	267,894	166,210	144,586
Total tons already built	865,984	763,132	471,962
Tonnage built and building	1,133,878	929,251	616,528
Dreadnoughts and battle cruisers built	14	8	2
Dreadnoughts and battle cruisers building	9	6	8
Dreadnoughts (capital ships) (7) and (8)	23	14	10
Pre-dreadnought battleships on hand	20	24	13
Pre-dreadnought armored cruisers on hand	9	11	13
Unarmored cruisers built and building..	43	15	14
Torpedo boat-destroyers built and building No 1	130	66	60
Submarines built and building No 2	32	46	15

Finally, we wish to emphasize the fact that because of the higher pay and better food and accommodations of officers and men in the fleet and ashore, and the higher cost of stores, provisions, navy yards, recruiting, etc., the *fixed charges of* our Navy are much greater than those of any other Of the total appropriation for the Navy, 1913-1914, of $140,736,526, no less than $100,000,000 has to be expended for fixed charges—pay, provisions, recruiting, navy yards, etc.—leaving only 25 per cent, or $35,825,695, available for new construction. Germany, whose fleet is manned by conscription, does not have to set aside as we do some $40,000,000 for pay, and hence, out of her naval appropriation of $111,288,618, she is able to set aside 47 per cent, or $52,179,113, for new construction

The Safe Aeroplane

RECENTLY the *Société Française de Navigation Aérienne* held at the Hotel des Ingenieurs Civils, Paris, a special public meeting in which the question of aeroplane safety and the prize of $80,000 offered for the invention which would most markedly advance safety, were discussed before a large audience composed of leading French experts. A translation of the most significant parts of their speeches seems especially interesting in view of the fact that the SCIENTIFIC AMERICAN anticipated and elaborated in an article on "Recent Improvements in the Aeroplane and What They Mean," on the 24th of January, on this side of the ocean, the novel points of view first revealed in Europe at that meeting.

The first speaker was Mr Archdeacon. After criticising the rules under which the prize was offered, and after calling attention to the fact that to establish safety by tests would be inconclusive if the devices were apparently successful and a crime if they were not, he said:

"The only competition for safety which would not be absurd in theory, could not be truly called a competition for safety.

"It would be held, for instance, under the following rules:

"Apparatus for two men; speed required, 60 miles per hour. Start for all competitors on the same day, for a round trip through France, covering daily 300 miles. Repairs permitted only with the tools and materials or spare parts carried aboard the aeroplane, the time required for repairing to be counted as flying time.

"No mechanic permitted to work at the apparatus except the two aviators.

"Obligation to land on difficult grounds and on an inclosed circle of 120 feet diameter around which a rope is stretched four feet above ground, which must not be broken under penalty of disqualification.

"An analogous rule could be established as to starting on a small area.

"I see, for instance, safety in an apparatus which will not be so very different from actual aeroplanes. It needs a good motor that will never fail, *with an enormous amount of surplus power*, all carried on a machine that is extremely substantial and *permits of a great range between its highest and lowest speeds.*

"Given such an apparatus, our good pilots will fly with it around the world."

Mr. Doutre, of stabilizer fame, the next speaker, said:

"The problem of safety for the aeroplane is complicated and deals with all branches of this novel industry. All progress in any line should be encouraged, for it is from the collaboration of various inventors that the best apparatus will originate, which, progressively perfected, will finally afford a better and better relative security."

The most novel and interesting contribution was that of Mr. J. de Saint Aubin, who substantially said:

"I was happy to learn of the opening of a discussion by the Société française de Navigation aérienne for the purpose of throwing some light on the delicate question of safety for the aeroplane. This really comprises two different problems—safety on the ground and safety in flight.

"If an aeroplane has to fly fast to escape becoming a plaything of the wind and the gusts, it must land at slow speed, without losing any of its lift on that account.

"Therefore, I am compelled to proclaim the absolute necessity of varying the incidence of the wings. Such an arrangement will not only greatly facilitate landing, but its action *during flight can be depended upon for avoiding the accidents which originate from positive or negative accelerations.*

"With wings of variable incidence the pilot can, at the moment of acceleration, regulate the incidence to the speed of the moment.

"With such an arrangement *there is still needed, as a useful accessory, a rudder of enlarged surface*, in order to retain control, no matter how much the speed might be reduced. Aviation owes it to Mr. Paul Schmidt, the very intelligent French constructor, that the problem of variable incidence has entered to-day the experimental stage"

There are now really two great solutions of the problem of safety, which the Jury of the Union for Furthering the Safety of Flight may pass upon as accomplished facts—"looping the loop," and wings of variable incidence.

These mean essential progress for the art of aviation, other things (stabilizers, instruments, etc.) are only accessories.

Conserving Waste

THE reclaiming of waste material in the manufacturing industries of the country often marks the difference between a profitable and unprofitable business.

The Williamsport, Pa., plant of the National Silk Dyeing Company has recently installed the most complete system in the world for the reclamation of pure tin from the waste bichloride of tin used in weighting silk, and it is asserted reclaims a higher percentage of tin than any other dye house in the world. This liquid tin is conveyed in a concrete channel to three large settling pits outside of the dye house, each one of which is thirty feet square and twenty-four feet deep. Baffling boards prevent any current. When the water enters the first pit the tin can be seen in suspension as it settles toward the bottom. The water clears somewhat in the second pit, and the tin is found nearer the bottom.

In the third pit the tin sludge has settled entirely, and can be seen as a whitish mass at the bottom of the pit. By the time it reaches this last stage of its journey as much tin is out of it as can be taken, and the water on top runs off into the river after being purified. From Saturday noon until Monday morning of each week these are cleaned. The tin sludge is then pumped from the pits into a tank at the top of the dye house, and from there run into large presses where practically all of the liquor is squeezed out of it. The sludge is then dried into a tin dross in specially constructed ovens, and then mixed with a suitable flux, heated in a reverberatory furnace, and the pure tin smelted out of it. About sixty per cent of pure tin is recovered in this way.

The Problem of the North River Bridge

To the Editor of the SCIENTIFIC AMERICAN:

In connection with the recent agitation for a bridge over the North River, it is a remarkable fact that no doubts are raised any more as to the practicability of the long span of 3,000 feet required from pierhead line to pierhead line. It was not so when the writer first published his plans, proposing that length of span over twenty-five years ago (1888). The necessity for a single span of nearly double the length of that in the Brooklyn Bridge arises from two considerations, which, however, were not accepted as conclusive for many years.

First, the rock foundation underlying the mud bottom of the river is from 250 to 350 feet below water, making the building of piers in the river, if not impossible, yet enormously costly. One single pier in the river would have cost over seven million dollars. That amount would pay for 60,000 tons of high-class steel, which added to the steel required for a bridge with piers in the river was more than enough to build a bridge without a pier in the river.

It is real economy in this case to build the bridge with a single span.

The second reason is that the United States Government would never permit piers in the river, even if the foundations would have been favorable, because of the obstruction to navigation and to the maneuvering of large steamers in and out of their docks.

The plans for a single span were criticised as impracticable and unworthy of serious consideration by engineers who posed as eminent engineering authorities at the time. The attacks upon the feasibility of a single span bridge resulted in the appointment of an engineering commission by President Cleveland when Secretary Lamont was in charge of the War Department (1894). That commission, headed by the late Gen. Charles W. Raymond of the Engineer Corps of the United States Army, after a lengthy investigation, declared a single span bridge over the river entirely feasible, and this had the effect of quieting criticism thereafter.

But while this economic feature of a bridge over the North River is settled, another important feature, which also bears upon its economy, should not be neglected, and that is, that it should be built with two decks, so as to give the largest possible carrying capacity, all of which will surely be needed by the ever-growing traffic.

There should be one deck for highway traffic, which includes roadways, promenade, and track for surface, elevated and subway connections, all of which can be accommodated on one deck within the great width the bridge must have to resist wind pressure. And on a lower deck, there will be room for eight railroad tracks, over which the trunk lines in New Jersey can come into New York. The cost will not be proportionately increased, because the same width of right-of-way and the same foundations can accommodate two decks as well as one deck.

The writer had made plans for such a double deck bridge, the location and construction of which had been authorized by the Government (in 1890) from the foot of 23rd Street in New York to Hoboken and the Heights in New Jersey, as shown in the accompanying view. That location was then considered the best for the needs of both sides of the river. It would not be so now. The bridge was intended to be built with the aid of the railroads in New Jersey. But in 1900 the development of electrical traction had brought submarine tunnels, as competitors, into being. While submarine tunnels are not cheaper, track for track, than a multiple-track long-span bridge over the North River, the tunnels have the advantage that they can be built a pair at a time and can be added as needed, while a multiple-track bridge must be built to final size at once.

The Pennsylvania Railroad did not choose to wait for the other railroads in New Jersey to join it in building a bridge, but determined to come in alone in tunnels to a station below ground, to be connected by tunnels under the East River also with the Long Island Railroad system. This fact stopped the building of a bridge across the North River for the time being.

In the meantime, the improvements in automobiles have been so rapid as to transfer this former vehicle *de luxe* for persons into the vehicle of greatest necessity for street commerce. All street vehicles are now carried across the North River in ferries.

The demand for swifter vehicle communication between New York city and the New Jersey territory opposite becoming louder and more urgent, has led to the demand for both tunnels and a bridge for highway traffic; but the equally urgent needs of the railroads have not yet been considered, mostly for the reason, it appears, that the entire project is yet in an embryonic condition, and has not yet been thoroughly studied. Another reason is that the railroads just now are struggling, under hostile legislation, for their very financial existence, and are not in a condition to assume new burdens of construction, no matter how much needed. But this condition cannot last forever. Saner views among the public and the law makers will ultimately prevail, so that the normal growth of construction and commerce will again go on

In the meantime, the railroad freight terminal problem in Manhattan is before the city authorities awaiting solution. It requires the crossing of the river with railroad tracks either through freight tunnels or over a bridge. A careful study of that freight problem will make it appear that the crossing over the bridge will be cheaper than through tunnels which would have to be nearly three miles long with heavy grades in them

The bridge proposition would then present itself in the following form:

Let the cost of a durable two deck bridge, extending from Ninth Avenue and Fifty-seventh Street in Manhattan to the Boulevard on the edge of the Palisades above the West Shore Railroad tunnel in New Jersey (8,330 feet long) be estimated at seventy-six million dollars, an ample amount (if built by private capital) to cover cost and contingencies of construction, right of way, cost of financing and interest during a construction period of seven years. The annual fixed charges would be:

For interest 4 per cent	$3,040,000
For sinking fund ½ per cent	380,000
For maintenance, taxes, administration	580,000
Total	$4,000,000

One half to be assumed by the railroads and one half by the two States.

The railroads' contribution of $2,000,000 to come from tolls, based upon traffic agreements. The share of each State ($1,000,000) to be paid in the form of a rental under an agreement running for the length of the amortization period (say fifty years). Payment of rental to commence only after completion of bridge. The two States would be entitled to the income from tolls on automobiles and from all local transit cars passing over the rapid transit tracks on the upper deck. For all other street traffic the bridge shall be free, the same as the East River bridges.

The revenue from wires and cables, belonging to telegraph, telephone and electric power companies, (not including those for the railroads or any service on the bridge) and from other sources to be equally shared by the railroads and the two States.

There is very little doubt that on these conditions the bridge can be built by private capital on condition that, when the cost of the work shall have been amortized, the tolls and rentals from railroads and communities shall be only enough to pay for maintenance, administration and taxes.

The great economy of a double-deck bridge over a purely highway bridge is apparent without further argument. Its construction without public funds is not only feasible, but highly desirable and advantageous from every point of view, because it can be built cheaper, better and quicker with private capital than it can be done as a work depending upon public funds The excessive cost and wastefulness of our public works is proverbial. It seems as if it cannot be helped under our systems of city and State administrations When the writer was Commissioner of Bridges of this city, he found it impossible to get construction work done at the same low prices as, for instance, railroad work of the same class. Many other conditions over which engineers have no control contribute to the excessive cost of work with public funds. Everyone of the four existing East River bridges cost 80 to 120 per cent more than the original estimates at the time they were authorized.

The share of the rental of one million dollars from each side of the river would commence only after the bridge is completed, and then it would hardly be felt by the tax payers within the benefited area in each State. In a few years the tolls from the local transit lines over the bridge would cover that rental, so that the taxpayers would then be fully relieved from paying anything. In contrast to such a condition of financing, observe the experience of the city of New York with the ferries to South Brooklyn and Staten Island There is now a deficit of nearly $900,000 a year (it was $896,214.18 in 1912) on the operation of those ferries, which has to be covered from general taxation The present prospect is that this deficit will not become less, but that it will be permanent and growing. The more passengers those ferries will carry, the greater will be the deficit. And a similar condition would probably be in prospect for a North River bridge built with public funds.

Although the traffic over the North River bridge would be ten times as large as to South Brooklyn and Staten Island, there would also be greater expense for maintenance and operation

There is sufficient experience on hand to warrant the view that the cost of that bridge built with public money would be indeterminate, and that its administration would become a duplicate of the deficit-producing Staten Island ferries, before which the city stands helpless.

It is only necessary that the railroad interests combine with the local communities for the construction of the bridge with private capital With a little patience and educational work it can be proved, because it is susceptible of proof that the bridge will mean a decided economy in the transfer of railroad freight as compared with the present method of carfloats

The freight terminal problem and the problem of local freight distribution is now proposed to be studied and worked out by experts for the city administration, with the aid of the Chamber of Commerce and the Merchants' Association of New York city, who have for years endeavored to have the subject thoroughly prepared, so that all future improvements for the harbor and shipping shall be done on a unified plan, of which the bridge over the North River will be an essential feature.

GUSTAV LINDENTHAL.

New York.

Span between towers, 3,100 feet. Height of towers, 650 feet. Width of floor, 150 feet. Capacity: On lower deck, eight steam railroad tracks; on second deck, six electric railroad tracks and one roadway; on third level, promenade.

The first design for a North River bridge, made by Gustav Lindenthal in 1888.

Protection From X-rays in Radiography

The Devices of Dr. Maxime Ménard

By Jacques Boyer

X-RAYS are exceedingly dangerous to scientists or doctors who are exposed to them, either daily or for single prolonged periods. The redoubtable emanations of the X-ray tube cause "burns," located, for the most part, on the hands of the operators. (Fig. 1.) This is due to their exposed position in radioscopic examinations. At times X-rays cause organic lesions of a deep-going character, necessitating, for example, the amputation of a finger or surgical interference of the face or forearm; they may even cause the death of professional manipulators in a relatively short space of time.

Dr. Maxime Ménard has succeeded in remedying this hazardous state of affairs. Thanks to special appliances and gloves capable of absorbing the most penetrating X-rays, he insures not only the absolute protection of the hands of the operator, but also that of the rest of his body. Indeed, the radiographic-room recently installed at the Cochin Hospital, according to the specifications of this erudite physician, is well worth a visit. Let us examine, in succession, the three principal constituent parts of this unique installation, (*a*) the sources of the high tension current supplying the X-ray tubes, (*b*) the protective devices of the apparatus for exploration and examination, and (*c*) the tubes generating the rays.

In Dr. Ménard's installation we find two units for the production of X-rays. One of these, used for radioscopy,[*] consists of an induction coil and an interrupter mounted, with certain accessories, on an oak stand. (Fig. 2.) The other, called the Gaiffe rotary commutator, contained in the cabinet on the left in Fig. 2, consists of a high tension, step-up transformer of the usual commercial pattern, furnishing an enormous difference of potential (160,000 volts) and a high tension rectifier transforming this alternating current into a continuous one which is supplied directly to the X-ray tubes.

We will now enter somewhat into detail with respect to each of these sources of current. The parts of the first are specially designed to withstand the formidable difference in potential obtained in the secondary winding of these coils, corresponding to a spark-gap of 30 to 35 centimeters. It is especially necessary to use an interrupter of particularly sturdy construction, such as the Blondel-Gaiffe mercury turbine The principal part of this piece of apparatus consists of a cone with multiple perforations, its lower extremity dipping into mercury. Upon its axis a motor is mounted. The whole is fixed to a metal cover fitted to a cylindrical tank inclosing the apparatus and hermetically sealed by a rubber gasket This tank is fitted with two taps for the introduction of the gaseous dielectric. When the cone revolves under the impulse of the motor, the mercury rises, by the action of centrifugal force, in the oblique channels of the cone and flows from nozzles in the form of a liquid conducting jet which periodically opens and closes the circuit of the coil with a frequency of 42 or 84 interruptions a second, according to the adjustment.

Besides this, in order to break currents of such considerable volume (50 amperes on the average) these interruptions take place in an atmosphere of illuminating gas which cools the ensuing sparks, and thus prevents the destruction of the metallic blades upon which the mercury is projected.

As to the Gaiffe induction coil, this is about 60 centimeters high and weighs 65 kilogrammes; its windings are submerged in a hydrocarbon insulating fluid of enormous electric rigidity, since a layer 5 millimeters thick of this dielectric resists a tension of 45,000 volts. Moreover, by reason of its viscosity, this substance retains its dielectric qualities to a remarkable degree, in spite of elevations of temperature during the course of operation.

Under these conditions, M. Ménard is able to traverse X-ray tubes with currents of 2/100 of an ampere with a difference of potential of from 70,000 to 80,000 volts. This enables him to make radiographs, as a matter of routine procedure, in a few seconds. But when the necessities of hospital practice demand it, this skillful practitioner turns to the Gaiffe rotating commutator, inclosed in a sort of cabinet (Fig. 2), which enables him to reduce the time of exposure to the fraction of a second.

This cabinet conceals within its interior a miniature electric plant (diagram, Fig. 3) of which the principal units are a high tension step-up transformer *T* and a commutator *M*. The first of these pieces of apparatus, inclosed in a tank of galvanized metal, connected with the terminals *AA'*, transforms the current furnished directly by the alternating circuit and gives to the secondary a tension of 160,000 volts, corresponding to a spark-gap of 30 centimeters. Above the transformer, insulated in the same manner as the induction coil described above, revolves the commutator which rectifies the alternating current. For X-ray tubes should always be fed with a continuous current in order to avoid causing their rapid deterioration.

The synchronous motor *M*, which revolves the commutator, turns with a speed exactly corresponding to the periods of the alternating circuit; consequently, the instant the alternating current reverses its direction, the mechanical rectifier makes its connections with the transformer and the tube in such fashion that the current does not change its polarity on the working circuit (i. e., through the tube) The only fittings projecting from the cabinet are the two large insulated columns, traversed by the high tension wires which it suffices to connect directly with the X-ray tube. A milliampere-meter, connected in series with the tube, permits measurements of the volume of the circulating current.

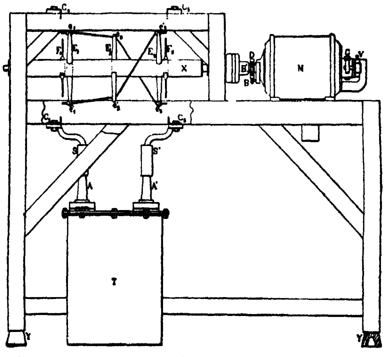

Fig. 3.—Diagram of the Gaiffe rotary commutator contained in the cabinet situated at the left in Fig. 2.

T, transformer; *AA'*, terminals; G_3, G_4, collectors for the rectified current; *M*, synchronous motor; *Y*, shock absorbers. *D*, collector for the clutch indicator

The marble slab mounted on the side of the cabinet seen in one of the engravings (Fig. 2) is used for cutting-in the synchronous motor which actuates the rotary commutator. As to the screen seen on the right of the same picture, this carries the regulating rheostat and serves, at the same time, to protect the operator from the X-rays emitted by the tube. Besides this, a device, termed an automatic cut-out (controlled by a special clock movement which permits the turning on of the current for periods of from 1/5 to 8 seconds as desired) completes the installation.

When it is desired to take a radiograph it is sufficient to close a switch, and the clockwork automatically breaks the circuit as soon as the time determined upon by the operator has elapsed.

Let us now describe the accessories of the radiographic installation of the Cochin Hospital, namely, the supporting standard of the X-ray tube and the exploratory apparatus. Inasmuch as the tube must be susceptible of being placed in any position whatever, so that it may be directed upon all parts of the body, according to the necessities of treatment, its supporting standard is a rather complex piece of apparatus, requiring perfect mechanical construction. In order to protect the operator, the tube is inclosed in a hemispherical shell of insulating material, opaque to X-rays. Metal plates cannot be used to absorb X-rays, in the vicinity of the tube, by reason of grave electrical disadvantages. It has been therefore necessary to turn to insulating materials, such as India rubber, in which heavy mineral substances have been incorporated, showing great opacity to X-rays. This protective shell serves also to carry limiting accessories which serve, when treating a patient, to confine the irradiation solely to the affected part, while protecting the rest of the body. These localizing devices terminate in tubes of crystal, opaque to X-rays, which bar the lateral passage of radiations while permitting the surgeon to observe the part to be treated.

In spite of the considerable weight of the protective shell, the displacement of the tube can be controlled from a distance with the greatest facility by reason of the perfect balancing of the whole. A diaphragm may also be mounted upon the shell which limits the passage of the rays to an opening, variable at will. The control of the diaphragm aperture is effected by means of a flexible connection whose extremity is within reach of the hand of the operator. Thanks to this disposition, the operator is enabled to make all radioscopic observations with a maximum of security. Besides this, a system of barrel springs supports the fluorescent screen upon which the shadows of the viscera are projected and balances exactly its weight. The arm for supporting this screen can be seen at the upper part of the tube standard (Fig. 4).

As to the table upon which radiographs are taken, or radiotherapeutic treatments administered (Fig. 5), this is a simple wooden table which presents the only peculiarities of having an inclinable back-rest and metallic attachments for immobilizing the patient.

But let us now come to the most original part of the radiological service of the Cochin Hospital, the protective device, designed by Dr. Ménard and of which we will borrow the description from the recent communication of this clever practitioner to the Academy of Sciences in Paris. This very ingenious apparatus consists essentially of three panels covered on the inner surfaces with sheet lead of a minimum thickness of four millimeters. Mounted upon a base, they form two wide dihedral angles in whose interior is placed the patient to be examined as well as the Crookes tube.

As is readily noted in the engraving (front page), the central panel is composed of three parts: 1. The fluorescent screen. 2. A movable lead screen. 3. A stationary lead screen. The first can be displaced vertically in grooves, like a sash, by the use of counterweights; the movable lead screen is arranged in like manner and can accompany the fluorescent screen in its movement, or can, on the contrary, be moved away from it.

This mobility of the two screens allows palpation of the patient's abdomen (Fig. 7) and, when once the palpation is concluded, they may again be brought into contact with each other. The patient is placed upon a very easily revolvable platform which the radiologist turns, according to his desires, in order to examine the patient in all pertinent ways. In addition, the fluorescent screen is provided with a covering of lead glass of thickness sufficient completely to absorb Roentgen rays. Finally, this apparatus, which assists the vision of the radiographer because it screens entirely the luminous tube, permits the radiography of the patient in the erect position by reason of the easy substitution of the radiographic plate-holder for the fluorescent screen.

Besides this, M. Ménard has devised protective gloves of an India rubber base combined with metallic salts of high atomic weight (85 per cent of lead compounds) (Fig. 8). With these gauntlets, four millimeters thick, not only the hands, but the wrists of the operator are completely protected from X-rays.

We will now finish our visit to the radiographic clinic of the Cochin Hospital by referring to the X-ray tubes used in this institution. For use in prolonged radioscopy and for radiotherapy, tubes are employed of a capacity of one milliampere; their anticathodes are made of platinum plates upon which the cathode rays are focused. The energy produced by the high tension current is concentrated, in consequence, upon the anticathode, whence an elevation of temperature of considerable degree results, even with currents of very slight

(Concluded on page [illegible].)

---

[*] Radioscopy is the term applied to the direct X-ray examination of a part of the body by means of a fluorescent screen Radiography is the process of taking an X ray picture by means of a photographic plate.—EDITOR.

The line of applicants at an Indianapolis factory.

A PAPER-GOODS factory that employs 200 workers, takes from 250 to 300 new employees or "learners" every year. This means that a large part of the cost of operation goes into training workers, or rather "breaking in" workers who do not stay long enough to repay this charge. In a certain large department store that employs regularly 1,000 workers, only about a fourth of the employees remain in the service as long as one year; the average length of service for the rest is about 14 weeks. In a wire factory employing 150 women workers, 450 to 500 "learners" are taken on every year.

An elementary student of arithmetic can see that there is something wrong in these establishments, but these establishments are not exceptional—they are typical. Yet neither the elementary student of arithmetic nor the "average business man" has taken the trouble to find out just what it is that is wrong. The latter has been inclined to blame the schools for sending him "inefficient" boys and girls, and the moving picture shows for making the workers restless, or the "agitators" for making them dissatisfied. The girls and boys for the most part have been too dazed to blame anyone. Perhaps more is to be gained in other ways than in looking for someone to blame.

It is true, to begin with, that the army of girls and boys that leave the elementary schools in the sixth to the eighth grades are extremely "inefficient" from the point of view of their prospective employers. But I am not ready to admit that the demands of these employers should be met by the schools. More than half the children leave at or about the age of 14 years, that is to say, as soon as the laws of the various States allow them to. At this age, most girls and boys are not sufficiently mature either physically or mentally to apply themselves to the sort of routine work that is generally offered to the beginner or the "learner" in most industrial or commercial establishments. That a few of them stick to the first job and work out of it into some sort of a career is fortunate for those few, but is no fair criterion of what we have a right to expect from the many. Nor is it an indication of what opportunities industry offers them. The fact is that most intelligent employers do not care for the young girl or boy, the cost of breaking him in is too great. As a result, the only kinds of work that these young people can get to do are those which are "easy to learn" by watching others, or by being shown once or twice. But these are just the tasks that lead to nothing; in a few short years the girl becomes a young woman, the boy becomes a young man, both without having acquired industrial skill or insight sufficient to bring in a living wage—and they become drifters or even unemployable. That this situation is extremely wasteful from an industrial point of view has been manifest to thoughtful business men for many years. One of the forces back of the movement for industrial education is just the recognition of the waste of potential in the drifting of the untrained workers.

A more dynamic recognition of this waste is to be seen in the scientific management agitation. Scientific management carries a promise of a new industrial revolution—not because it has already brought about an immense increase in the productivity of labor, but because its assumptions and principles are radically different from those upon which most industry in the past has been carried on. Since the beginning of the industrial revolution brought about by the introduction of machinery and factory methods, managements have depended upon expensive machines and cheap workers to produce profits. Closer competition has simply meant the refinement of machinery, the greater division of labor and the speeding up of the worker. Scientific management goes beyond this stage of industry, for it involves almost consciously a social revolution; it has become aware of the "human factor." It has discovered that whereas an individual pioneer may exploit the soil or the forest and leave future generations to take care of themselves, the community as a whole—since its life transcends that of the individual—cannot afford to do so; and it has become active as "conservation." It has discovered that whereas the individual exploiter may squeeze the blood from two or three successive gangs of workers, the railroad, or the manufacturing corporation, which transcends the lives of the individual workers, may not operate on this basis.

The ordinary manager gets what workers he can, any way he can, extracts whatever services from them that he can, and then replaces them with other workers. Scientific management undertakes not only to train each worker for his particular task; it undertakes to select each worker for the particular training. The task of the employment manager is no longer that of counting off so many hands from among the applicants; it is virtually to select pupils for special training within the works or store. It is an application to the human material of the scientific management principle of "efficiency of distribution." It recognizes the fact that to be good economically, a man must be good for *something;* and that one man may be good for one thing and quite worthless for another. It seeks then to put each worker where he will do the most good.

The work of the expert to redistribute the workers in industry is necessary because the workers have come to their jobs in the most haphazard way. This means great economic waste inasmuch as there is a great deal of drifting and shifting, inasmuch as there is a great deal of "internal resistance" involved in the fact that people are trying to do work for which they are by nature *unfitted,* inasmuch as the work lacks enthusiasm. But a still greater waste is involved inasmuch as the casual worker is not a happy worker, does not get from his work those esthetic and emotional satisfactions that distinguish men from machines and donkeys; and the worker who has not found his particular work is a casual worker. But this means most of the workers. Economic efficiency, as well as the higher social efficiency, calls for a more effective distribution of the workers.

The vocational guidance movement, which began to take on a definite form with the work of the late Prof. Frank Parsons (who fished for talents among the young people that patronized the Civic Service House in Boston), has expanded rapidly in a few years and seems now to offer a satisfactory basis for bringing together various forces that ought to work together but that have not been able to find a common working basis. The work started by Prof. Parsons is now continued by the Vocation Bureau of Boston under the direction of Mr. Meyer Bloomfield. In co-operation with employers and with the school system, this form of social service is rapidly assuming a prominent place in the activities of a progressive community. The business man who wanted the schools to give him ready-made office boys and machine operators may find that he can help the schools to giving him something even better. The school man, who was naturally suspicious of the clamor for "industrial education," may find that it is possible to reorganize the school to meet the new demands without losing any of the ideals for which he has stood—indeed, with a good prospect of strengthening the hold of his ideals upon the whole community.

Like all new ideas—like the efficiency movement itself—vocational guidance is exposed not only to a great deal of misapprehension, but also to a great deal of misapplication and abuse. Thus, the phrenologists and astrologers, pressed by science and the spread of education, find in it a new lease of life; for they can add a new high-sounding phrase to their armament of flub-dub and quackery. Or an old-fashioned exploiter looking for the latest wrinkle finds in vocational guidance a quick way for reducing the fee he is perforce obliged to pay to the employment agencies. But vocational guidance is neither an application of astrology nor a substitute for the employment agent. It is simply an attempt to introduce organized knowledge into a field that has been too long left to empiricism and blind chance. It is the effort to give the individual the benefit of competent counsel in the matter of directing his preparation for his major work in life.

Every reader is familiar with the street car conductor who ought to be an opera singer or statistician; you know the physician too, who ought to have become a plumber. Both lacked guidance in making their plans from year to year, while they were young. Surveys made in several cities during the past four or five years have brought out the fact that much of the drifting and floundering can be charged directly to the schools. This is true not because the schools have been inefficient in doing their special work; on the contrary, they have been increasingly efficient in this work for many years past. But the schools have been remiss in that they have not with sufficient alacrity adapted themselves to the changing conditions of social and economic life. Nearly three fourths of the children who leave school when the law allows, do so not because of direct economic pressure in the home, but because the school has lost its grip upon the children. This is to be explained by the fact that the schools continue to give to all the children just that particular pabulum which was satisfactory a generation or two ago to a small fraction—a selected fraction—of the children. But the mass of the children are different from that selected fraction in just this, that they are thing-minded, motor-minded, not word- or symbol-minded, like their teachers.

The result of this failure of the schools shows itself not only in its inability to hold the pupils, not only in the drift and waste of the best years of the children's lives, not only in the subsequent inefficiency—both civic

(Concluded on page [illegible].)

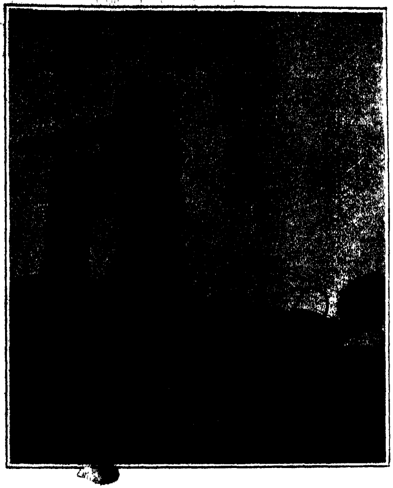
Guns on Aeroplanes

By John Jay Ide

AT the last Aeronautic Salon in Paris were shown several aeroplanes equipped with Hotchkiss quick firing guns. In almost every case, however, the firing arc was extremely limited owing to interference by parts of the aeroplane. Exception may be made in favor of the gun mounted on the Borel monoplane, which had its bow clear owing to the rear position of the propeller. Here again, however, there was an objection in that the gun had to be operated by the pilot, the passenger being placed behind.

The invention of M. Loiseau seems to solve the difficulty of fitting guns to present day monoplanes. As shown by the accompanying photograph, the arrangement consists in attaching the gun to a support braced to the mast and fuselage. The support is high enough to enable the gun to fire over the tractor even with considerable depression. The marksman is protected in front with a shield of four-millimeter armor, and has a light railing at the sides and rear. Granting the efficacy of the shield, the position of the passenger is an extremely exposed one. Also the pilot's view is somewhat interfered with notwithstanding the small sections cut out of the trailing edges of the wings adjacent to the fuselage, which allow him to see the ground. On the whole, however, the gun placing is the most satisfactory possible in tractor screw monoplanes.

The mitrailleuse is fitted to a military type two-seated Deperdussin. Trials commenced February 10th at Villacoublay, near Paris, under the control of Capt. Destouches of the French army. The pilot, Prévost, took up a mechanic to act as marksman. On February 14th the trials were renewed, this time under the observation of Gen. Bernard, Col. Estienne, and several other army officers of high rank. The passenger-marksman was the inventor, M. Loiseau. He operated the gun while the monoplane was on the ground, in full flight and gliding. The accuracy of the shooting while in the air was not remarkable, but it is a mere matter of time before that is obtained. The practicability of operating a gun in this position was fully proved.



The aerial marksman in action.

A Self-steering Farm Motor

By Herbert I. Washburn

THE application of the gasoline motor to agricultural work is of great interest to inventors at the present time. A solution of the question has been obtained for the big farms of the West in the form of the gasoline tractor, but this does not meet the requirements of the irrigated truck farms and gardens of the Eastern and Southern States.

The great need of the country is an efficient helper for the owner of the one-man farm; a machine that will work effectively and make him less dependent upon hired help. No hand steered machine can meet this requirement because the expense of the operator takes $500 per year off the profit of the farm. This was unavoidable with the use of the horse as motive power, but as the gasoline motor is an automatic power source, its correct use requires automatic steering.

Here is a system which has been worked on a practical basis by the writer. It requires compliance with certain mechanical conditions. The farmer who wishes to make use of it must be willing to abandon the old traditions of extensive farming. He must be willing, if necessary, to sell the hillside farm inherited from his grandfather and lay out a new farm to meet those conditions. This is an easy matter with young men just taking up intensive farming, and with those migrating to new localities.

The farm must contain one or more circular areas of any size, up to about ten acres each in area, reasonably level, and irrigated preferably by the tile system. Thus, a farm in central Florida would consist of the usual ten-acre square, with a seven-acre circle in its center, the remaining corners, three acres in area, being occupied by fruit trees, buildings, etc. In the center of the seven-acre circle, the center post shown in the accompanying photograph would be permanently installed. At the top of this post, which is strongly guyed, is seen an iron drum. This drum is indexed and locked by the small handle on the side of the standard. Attached to the iron drum is a slender steel wire, tempered and tin coated. This wire passes through the guide pulley shown, and then to the steering lever of the implement some distance away. At each revolution of the implement around the field, the wire wraps once around the drum, hence the circumference of the drum determines the swath of the implement. Between the frame and the steering lever of the implement a strong spring is attached tending to steer the implement away from the center post. The steering wheel has a deep flange in order to resist side pressure and is mounted in a ball-bearing head. About two pounds pressure at the end of the steering lever is sufficient to guide the implement. Since the tension of the steel spring (and of the steering wire opposing it) is about fifty pounds, the steering lever is obliged to follow an exact spiral path.

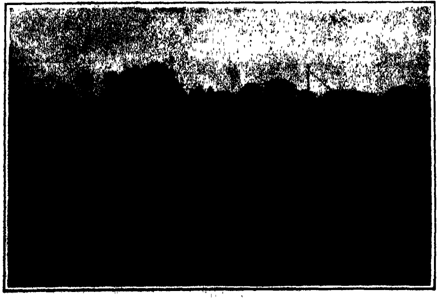
Center post about which the tractor runs.

Repeated runs with the experimental implement shown in the accompanying photograph, starting at a radius of about 200 feet and finishing about 20 feet from the center post, showed no visible variation from the path first struck out A plow jointer was used to indicate this path. A door check was made use of to prevent any undue vibration of the steering lever The slight dancing of the steering wire was desirable, as it obliterated the last vestige of friction in the steering head

The framework of the implement is intended to be such as will facilitate the attachment of all the devices used in row-crop farming, such as plows, ridgers, cultivators, sprayers, etc. Also conveniences for use in connection with hand steering, such as mowing bar, carrying rack, etc.

An improved style of implement has been designed having motive power applied to both rear and forward wheels, both wheels being pivoted so as to work between closely set rows of plants. About 90 per cent of the weight of the machine is on the two drivers, giving a strong adhesion. The remaining 10 per cent weight is on the wheel at the end of the beam. The height under the beam is about three feet, permitting the cultivation of truck, tobacco, cotton, etc., of that height A safety device is provided to stop ignition in case of breakage of the steering spring or wire.

The steering action of the tractor was found to be very dependable in the experimental runs, requiring no attention whatever. The unwinding of the wire from the drum is accomplished while the implement is being run out of the field by hand steering. The steering wire is then suspended ready for use at the next operation. With a dependable gasoline motor, having a positive lubrication, etc., two six-hour runs per day, without an attendant, are possible, placing the farmer on an equal footing with the manufacturer, with his automatically-fed, power-driven machines.



Gasoline tractor that runs a spiral course without an attendant.

Fodder Equivalents

COMPARATIVE tables of the nutritive value of various foods, and the proportions of proteids, fats, and carbohydrates they contain, have long been available for students of human dietetics. That similar tables would be equally valuable to breeders of domestic animals is obvious According to *La Revue* (Paris) such tables are now furnished by Prof. Mallevie, who holds the chair of zootechnology in the National Agronomic Institute of France

"For the first time we are in possession of fodder equivalents. We now have a precise knowledge of the value to horses or cattle of definite quantities of hay, straw, clover, flax-seed cake, and beets, in what measure they can be substituted for each other to attain the same result and what economy or other advantage may result from such substitution"

M. Mallevie shows that 6 pounds of meadow hay give the same alimentary result as 12 pounds of wheat-straw, 2¾ pounds of wheat bran, 22 pounds of beets, 5½ pounds of clover hay, or ½ pound of flax-seed cake.

"These figures indicate what he calls the unit of fodder His table shows how, in default of one equivalent, another may be used without inconvenience, quantities being combined according to circumstances."

Breeders will thus be enabled to compute profits more definitely, and can find by experiment what food gives the largest returns in meat, milk, butter, etc With reference to its cost, it should be remembered, however, that two animals fed on the same ration may vary in power of assimilation, so that one will extract better results per kilo than the other.

Duplicating Charts by Zincography.—The United States Hydrographic Office has recently installed a plant for the reproduction of foreign charts by zincography The hydrographer states in his last annual report that this work will occupy at least four years, but when it is completed the Navy will be practically independent of foreign sources of supply for charts.

A Great Telescope for Canada

THE Canadian government will soon possess a more powerful reflecting telescope than any now in existence. It has been referred to in the newspapers as "the largest telescope in the world," but this description is misleading for two reasons; first, because its aperture, 72 inches, is to be the same as that of the famous Parsonstown reflector, built by Lord Rosse in 1842; and second, because by the time the Canadian instrument is completed it now seems likely that the 100-inch reflector which has long been under construction for the Mount Wilson Solar Observatory will also be ready for use. The Canadian telescope will, however, be a much more efficient instrument than Lord Rosse's. Not only will the mirror be much superior, but the mounting will enable the telescope to be worked to the full advantage. The Parsonstown reflector has an altazimuth, not an equatorial, mounting, and is operated under such difficulties that comparatively little use has ever been made of it.

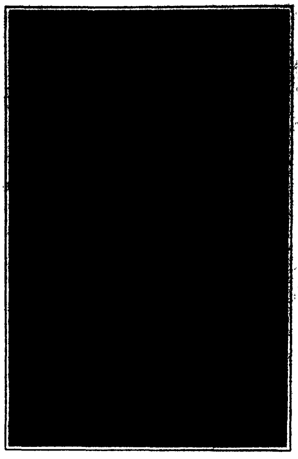
Contracts for the new telescope have just been awarded to J. Brashear for the mirrors and other optical parts, and to Warner & Swasey for the mounting. The disk for the principal mirror will be made by the St. Gobain glass works, in Paris, but all the grinding and figuring will be done in this country. The total cost will be *nearly* $100,000. Inasmuch as the instrument is intended primarily and notoriously for work of no immediate practical benefit, viz., the spectrographic measurement of radial stellar velocities, this sum represents a very notable contribution to pure science on the part of a government.

The telescope will have a parabolic mirror of 72 inches clear aperture and 30 feet focal length, with a central hole 10 inches in diameter. The mounting is to be similar to that of the Ann Arbor and Melbourne reflectors, with a skeleton tube at one side and nearly midway between the bearings of the long polar axis, the balance being restored by the declination motion mechanism and by counterweights at the other side. Both polar and declination axes will be carried entirely on ball or roller bearings, in place of the usual plain bearings for collimating and a complicated system of counterweighted rollers for relieving the friction. The construction will also be simplified in other respects, e. g., all fine circles will be omitted, as will the slow motion arm in right ascension. It is characteristic of twentieth century technique in astronomy that, although the new telescope will have a full set of oculars for visual observations, no programme of visual work is contemplated. Nowadays the camera takes the place of the human retina. The main purpose of the instrument will be the measurement of motion in the line of sight of stars fainter than the fifth magnitude; a task beyond the light-gathering power of nearly all existing telescopes. For such work the telescope will generally be used in the Cassegrain form; the light from the main mirror, converging toward a focus, will be received by a second hyperboloidal mirror of about 19 inches aperture and 10 feet focus, placed about 23 feet above the main mirror. The light passes thence down through the hole in the main mirror, and the star images are formed about three feet below the latter. Here the spectrograph will be placed. For the fainter stars of low dispersion the spectrograph will probably be placed at the prime focus. An investigation of the atmospheric conditions in different parts of Canada is now in progress, to determine where the telescope will be located.

Nebuchadnezzar as a Builder

By Edgar J. Banks

PROBABLY the greatest builder the world ever had was Nebuchadnezzar, King of Babylon from 604 to 561 B. C. There is hardly a ruin in Babylonia which does not show traces of his work. Nearly everywhere in Mesopotamia, and even in Persia, are found bricks bearing his name. He delighted in restoring the old temples. He surrounded defenseless cities with walls and moats. He confined the rivers to their courses with huge brick embankments. Shortly before his time Babylon was completely destroyed, and its foundations were scraped into the river, but he rebuilt and enlarged the city. The temples with which he adorned it amazed even the travelers from distant Greece. The walls surrounding it were one of the seven wonders of the ancient world. Fortunately it was Nebuchadnezzar's custom, whenever he built or restored a temple, to write a long description of his building operations upon a cylinder of clay, and to bury the record in the walls that future generations might read of his work. His wish has been fulfilled, for during the past two years several of the cylinders have been discovered by Arabs, and have found their way to Europe and America.



A finely molded burned clay cylinder of the great builder, Nebuchadnezzar.

The inscription is in three columns, with 145 lines of cuneiform writing, and so well preserved that every one of the fifteen hundred wedge groups is perfect.

One of the last of the cylinders to appear, and now in the possession of the author, was discovered by Arabs in a ruin called Wana-Sedoum, or more correctly Wannet es-Sa'dun, a day's journey to the south of Babylon on the Euphrates River. It mentions the ancient name of the place as Marad, and thus another city is *added to the map of ancient Babylonia.* The cylinder is really a truncated cone, 8½ inches high and 18 inches in its greatest circumference. It is of finely molded clay thrown upon a potter's wheel, and built up as if it were a vase without a bottom. The interior walls distinctly show the finger marks of the ancient potter. The walls are very thick. After the cylinder was inscribed, it was burned until the clay became a compact sand-colored stone. The inscription is in three columns, with 145 lines of cuneiform writing, and so well has it been preserved that every one of the fifteen hundred or so of wedge groups is perfect.

The first part of the inscription is familiar, because it is practically a duplicate of the records upon similar cylinders discovered elsewhere. Nebuchadnezzar begins in his boastful way by telling who and how great he is. Then follows an account of the building of the great walls of Babylon "mountain high," and of the restoration of several temples in Babylon and other Babylonian cities, including the Biblical cities of Ur, Larsa, and Erech, and of the tower at Borsippa, which travelers have called the tower of Babel. His account of how the gods instructed him to make a charm against disease, and to bury it in the foundation of the temple, hints at the superstition of his time. His prayer to the goddess Ninharrak shows his piety and command of beautiful language.

The last part of the inscription is of historical importance, for it is new. In it he speaks of restoring the temple at Marad, and ends with a prayer to Lugal-Marad, the local deity of the place. A translation of the inscription is as follows:

"I am Nebuchadnezzar, King of Babylon, the great, the mighty, the favorite of Marduk, the powerful prince, the beloved of Nabu, the ruler who knows not weariness, the protector of the temples Esagil and Ezida, who is obedient to Nabu and Marduk his lords, who does their bidding; the wise Lord, the darling and the joy of the heart of the great gods, the first-born son of Nabopolassar, King of Babylon.

"When Marduk, the great lord, made me the rightful son, to rule the land, to be the shepherd of his people, to care for the city, to rebuild the temples, he bestowed upon me his great power. Tremblingly I was obedient to Marduk, my lord. I completed Imgur-Bel and Nimitti-Bel, the great walls of Babylon, his mighty city, the city of his exalted power. At the entrance of the great gates I erected strong bulls of bronze, and terrible serpents standing upright. My father did that which no previous king had done. With mortar and bricks he built two moat walls about the city, and I with mortar and bricks built a third great moat wall, and joined it and united it closely with the moat walls of my father. I laid its foundations deep to the water level; I raised its top mountain high. I constructed a moat wall of burned brick about the west wall of Babylon. My father built the moat walls of the Arahtu canal securely with mortar and brick. He built well the quays along the opposite shore of the Euphrates, but he did not finish all his work. But I, his first born son, the beloved of his heart, built the moat walls of Arahtu with mortar and bricks, and joining them with the moat walls of my father, made them very solid.

"Esagil, the wonderful temple, the palace of heaven and earth, Ekua, the temple of Marduk, the lord of the gods, Ka-hilisug, the dwelling place of Zarpanit, Ezida, the temple of the king of the gods of heaven and earth, I clothed with shining gold, and made bright like the day.

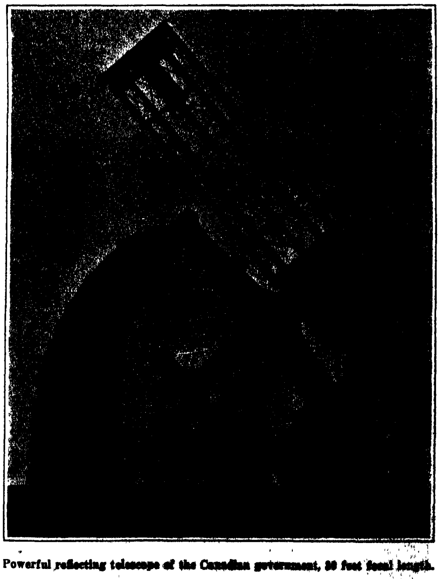
"Ezida, the favorite temple, beloved of Nabu, I restored in Borsippa. With gold and jewels I made it beautiful like paradise. I overlaid with gold its great beams of cedar, and arranged them by three to cover Emahtila, the shrine of Nabu. I rebuilt and made lofty Emach the temple of Ninharsag, in the center of Babylon. . . .

"I did a thing which no king before me had ever done. To the west of Babylon, at a great distance from the outer wall, I constructed an inclosing wall 4,000 cubits in length about the city. I dug its moat to the water level. I walled up its sides with mortar and burned bricks, and I united it securely with the moat wall of my father. Along its edge I built a great wall of mortar and burned bricks mountain high.

"I rebuilt Tabisupurshu, the wall of Borsippa. To strengthen it, I built the wall of its moat about the city with mortar and burned bricks. In Borsippa I rebuilt the temple to Tur-lil-en, the god who breaks the weapons of my foes. Ebarra, temple of Shamash in Sippar, Eanna, temple of Ishtar in Erech, Ebarra, temple of Shamash in Larsa, Egishshirgal, temple of Sin in Ur, the sacred temples of the great gods, I restored and completed.

"The support of Esagil and Ezida, the rebuilding of Babylon and Borsippa, which

(*Concluded on page 314.*)



Powerful reflecting telescope of the Canadian government, 30 feet focal length.

The main purpose of the instrument will be the measurement of motion in the line of sight of stars fainter than the fifth magnitude.

Safe Moving Pictures

The Inventions of Nicholas Power

By Arthur J. Lang

Fig. 1.—A cheap moving picture theater, whose frequenters are dependent for their safety on the fire prevention devices which eliminate the hazard of the rapid-burning film.

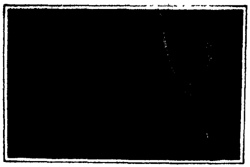


Fig. 2.—The operator of a moving picture machine takes his life in his hands in operating machines not equipped with adequate safety devices or in failing to properly maintain these devices in service when operating modern high-grade machines. The character of operators is a big factor in averting panics, always potential in film theater audiences, as modern conditions require highly intelligent operators.

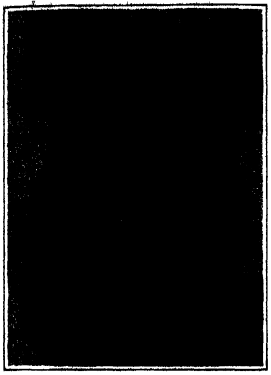

Fig. 3.—The film valve consists of a chute C and four rolls, A, A, B, B. A flame cannot pass the rolls, nor through the chutes to the film magazines.

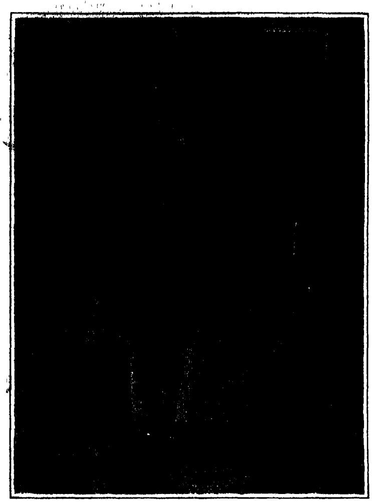

Fig. 4.—A characteristic type of improved electrically-driven motion picture machine in which fire hazards have been minimised and various projection faults (flicker, etc.) practically eliminated.

Fig. 5.—How the film is protected above and below the aperture by the shield U, the shield L, the guard plate G. Lever O used to pull loop.

EVERY day nearly ten million persons flock to the film theaters in the United States. The pictures that flicker before their eyes are photographic images imprinted in strips of film that if ignited burn with the explosive rapidity of smokeless powder. These strips of film move across a stream of concentrated light while pictures are being shown, light so powerful that the rays if focused on a surface of wood could bore into it with the speed of a flame. Were it not for its rapid movement the film would blaze up immediately if the light were not cut off.

Yet films ignite in projecting machines but rarely, if ever, in this country; at the worst, mere holes burned in the strip. A picture or two is cut out, and after the clipped ends are cemented together, the film is ready for another run.

But in other countries south of the United States and abroad, the results of film ignition in projecting machines have been far more serious. Recently fifty-eight children, sixteen women and one man were killed in a panic precipitated by the ignition of a film in a picture theater in Surabaya, Java. One hundred and thirty-one persons, chiefly children and women, were killed and injured, May 27th, 1912, in a film show in Villareal, Spain. The picture machine was not equipped with a take-up reel, and as films were run through the machine they were allowed to pile up on the floor. The film carrying the final pictures of the performance caught fire and ignited the heap of other films on the floor. Since then a number of other horrors of a similar character have occurred abroad, and in the Latin republics of Pan America. But the United States has been singularly free from catastrophes of this sort and magnitude during recent years. The chief reason is that more progress has been made here than in other countries in perfecting the safety features of projecting machines that minimise, or eliminate entirely, fire perils in films. Much of that progress is due to the inventive genius of Nicholas Power of New York.

A motion picture machine comprises two parts: A source of light (the lamp), and the mechanism for operating the film (the machine head). Manifestly safety lies in keeping the inflammable film away from every possible source of ignition, and so closely confined within the machine head, that if ignited by the rays of light, the film will not burn more than a few inches at the worst.

In the early machines films were anything but closely confined. In the "spool-bank" type used until 1896 the film passed over and under the lamp house to and from a box containing series of spools upon which it was threaded. At that time films were made only in lengths of seventy-five feet with ends jointed together, forming endless belts. Frequently the films would touch the lamp house and promptly ignite. After a number of such accidents the belts of film were laid in glass-covered wooden boxes mounted under the machine head.

When longer films began to be used they were wound on reels. A film to be shown was wound on a reel mounted on a bracket clamped to the top of a machine head. As the film was run through the machine, it was spilled on the floor under it. Not only did spilling the film add to the fire peril, but the film itself was scratched or broken and the pictures damaged. Even in New York city in the days when motion pictures "chased" vaudeville performances in large theaters, it was not an uncommon occurrence for films to fall over the rails of balconies, behind which projecting machines were located, into the crowded auditorium below.

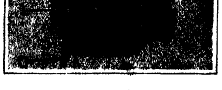

Fig. 6.—The shutter S automatically closes and cuts off the light when the machine stops.

To preserve the pictures some machines were fitted with bags hung so as to receive the films as they were run out. In some cases films were wound by hand on take-up reels instead of being spilled in bags.

In 1904 Nicholas Power devised a take-up or rewinding reel that would automatically vary its speed in proportion to the increasing diameter of the circle of film as it wound on the reel, the speed of the reel being greatest at the initial operation of winding and automatically decreasing as the film wound up, so that the tensional strain would be uniform throughout the winding

Power's take-up device comprises a spindle, which carries the reel, and the driving pulley which is driven by a belt from the machine-head mechanism. The pulley is composed of two separate plates One plate is made fast to the spindle driving the reel, the other rotates loosely on the spindle, but is held against the face of the driving plate by a spring coiled around the spindle. As the film winds on the reel and begins to pull, the spring on the spindle yields, allowing the driving belt to run on the loose pulley plate and slip in the driving side. Also the device is arranged to be driven by a chain or a gear.

While the take-up device improved the operation of a machine it did not lessen the fire hazard much, as the film was exposed on reels over and under the machine head. Immediately following the development of the take-up device, Power introduced metal magazines (*M*¹ and *M*²) Fig. 4, to contain the feed and take up reels; and to prevent the flames of burning films from entering the magazines, he devised a special form of valve, Fig. 3, which allows the free passage of film in or out of a magazine, but which effectively stops the progress of combustion in a blazing film.

The film valve (Fig 3) consists of an elongated chute *C* and four rolls *AABB*. The upper valve shown in the figure is mounted in the inside lower corner of a feed reel magazine *F*, and the lower in the outside upper corner of a take-up reel magazine *T*. The rolls *A* are fixed guide rolls which keep the film from rubbing against the walls of the chutes The rolls *B* are idler rolls whose journals bear in slots *B*¹ cut at angles so that no other force than gravity will be necessary to hold the rolls against the film, thus preventing tensional stresses. The rolls have outer flanges which press against the margins of the film, so that nothing touches the emulsion or picture surface. It is practically impossible for a film to burn past the idler rolls and their companion fixed rolls, but should that occur the blaze could not enter the chutes.

Machine magazines for film reels *M*¹ and *M*² (Fig. 4) are made of heavy Russia iron in square forms, without solder. The upper or feed reel magazine *M*¹ is mounted on a rigid spider which is attached to the machine head frame. The lower or take-up reel maga-

RECENTLY PATENTED INVENTIONS

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN

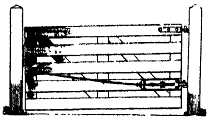
Pertaining to Apparel.

DRAW STRING—BERTHA CLARK, 228 52nd St., Brooklyn, N Y. The invention provides a draw string or band for use in the hem of the gathered waistband of a washable garment and arranged to allow of conveniently and quickly removing the draw string or band prior to washing the garment, and to permit the ready insertion of the draw string or band after the garment is washed.

Of Interest to Farmers.

REVOLVING HARROW.—J. M. BASSLER, Marion, Ohio The improvements in this case are embodied in two circular harrows arranged horizontally and mounted on axes having bearings in draft bars whose front ends are loosely connected by a draft appliance, their rear ends being coupled elastically by a bowed plate spring which serves to hold the peripheries of the harrows in frictional contact, so that the rotation of one aids rotation of the other, which enables the harrow teeth to clear themselves of adhering turf, vines, or other trash Means provide for enabling the harrows to conform more easily to inequalities of the surface over which they are dragged

HINGE—T MITCHELL Oquawka, Ill. This inventor provides an adjustable hinge to be used with fence gates, to compensate for settlement in the gate, or in the hinge post, or to be adjusted for holding the outer swinging end of the gate in raised position to clear any obstruction which may occur in the path of the gate. An object of the invention is to provide adjusting means for the hinge, which may be operated from the outer end of the gate, so that the leverage afforded by the length of the gate may be taken advantage of in raising the gate, while the adjusting means is operated



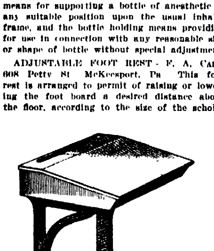
HINGE FOR FARM FENCE GATES.

Of General Interest.

RETAINING DEVICE A Q WALSH, 2 W 47th St, Manhattan, N Y, N Y This invention provides a device for holding fountain pens, pencils, rules, eyeglass cases, clinical thermometers, and similar articles securely in position in a pocket of a vest or other garment while the latter is worn, and arranged to prevent the article from accidentally falling out of the pocket on the wearer stooping or making other bodily motions

BOTTLE HOLDER FOR CHLOROFORM INHALERS - L. DROSIN, 1666 Lexington Ave, New York, N Y. The invention comprises means for supporting a bottle of anesthetic in any suitable position upon the usual inhaler frame, and the bottle holding means providing for use in connection with any reasonable size or shape of bottle without special adjustment

ADJUSTABLE FOOT REST - F. A. CARR, 608 Petty St McKeesport, Pa This foot rest is arranged to permit of raising or lowering the foot board a desired distance above the floor, according to the size of the scholar using the desk on which the foot rest is applied, and to allow of folding the foot rest and swinging the same into vertical position between the standards of the desk and below the table thereof when dispensing with the use of the foot rest or for other reasons



ADJUSTABLE FOOT REST FOR DESKS, ETC

WATER SKEE.—V VOLLER, Bemidji, Minn This invention is in the nature of a water skee, the object being to provide a strong, durable, and safe construction which may be readily propelled through the water and effectively guided in its course. The action is substantially similar to that of skees on the snow, and the knack of actuating the water skee is readily acquired.

TOOTH BRUSH—C. E. CARROLL, Newport, Ark As the formation of tartar begins underneath the gum margin below the necks of the teeth, adheres to the roots and remains as a permanent irritant to the gum, and as no brush in general use is effective in preventing such condition, the present invention has been devised to prevent the lodgment of foreign substances within the free margin of the gums

Hardware and Tools.

LOCK—W MEISS, 1951 Seventh Ave., Manhattan, N Y, N Y. This invention comprises a removable bolt adapted to secure in position a hasp used for fastening a door or the like, a movable member having means for holding the bolt in place, and key-controllable means for actuating the movable member, the last named and the hasp being positioned at the same side of the door.

FOLDING STEP LADDER.—J. DYBECK, care of M Stenabaugh, Box 464, Sault Ste. Marie, Mich. In the present invention the step section is pivotally suspended by a hanger at the top, the hanger constituting a plate spring, and a link connects the step section with the stand or frame below the hanger, the arrangement being such that in the swinging of the ladder to an inner position within the stand, the hanger is placed under tension so as to force the ladder downwardly and by its engagement therewith hold it securely within the stand.

Heating and Lighting.

VALVE FOR GAS BURNERS.—E S ALLEN, 517 W 134th St, New York, N Y. The purpose of the inventor is to provide a valve for gas burners arranged to permit convenient adjusting with a view to regulate the amount of gas passing from the service pipe to the burner and to be automatically closed by a movable member of a stove so that the gas is shut off from the burner

Household Utilities.

BED PAN - A B KNOWLTON, care of Knowlton Hospital, 1515 Marion St, Columbia, S C. The pan is constructed with a central, longitudinal, primary chamber or receptacle and with an overflow receptacle which partly surrounds the primary one, and a third receptacle into which both the others finally discharge their contents Such final receptacle is located at one end of the pan and holds the excreta safely when the pan is carried, in vertical position like a pail, by means of a handle located at the opposite end of the pan The final receptacle is constructed with a flat head or end so that it may be supported in vertical position upon a floor or other flat surface

Machines and Mechanical Devices.

CHRONOMETER ESCAPEMENT—W E. WALKER, Woodstock, Ohio. The purpose here is to provide a detached escapement in which the balance receives impulse direct from the teeth of the escape-wheel, without the use of guard pins, banking pins, or springs, and which will effectively perform its function in the face of hard or rough usage

BOAT PROPELLING MECHANISM—J. B TRESCOTT, care of Wisco Supply Co, 7th and 8th Sts and Clark Ave, St Louis, Mo., and R C Busch, St Louis, Mo. The invention provides motor units arranged for propelling boats; provides means for demounting and remounting units to augment or diminish the motive power for propelling boats or the like; provides a multi unit prime mover for vessels, adapted for temporary installation; provides units for propelling shallow-draft vessels, provides means for harnessing said units to permit shifting thereof for use as aids in steering the vessel, and provides means for harnessing the units to change angle of operation thereof relatively to the keel of the vessel to which they are applied

SCALE—V O. KLINGLER, Slayton, Minn. The principal object of the invention is to provide an improvement especially adapted for use with the scales, whereby the valves will operate more easily, the use of the improvements also tending to save the wear on certain of the co operating parts.

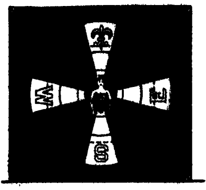
JIGGING MACHINE.—O. H. BOHM and W. M McCOY, Birmingham, Ala Address the former, 725 Sergeant Ave, Joplin, Mo. An object of the invention is to provide a device in which the working parts of the plunger reciprocating mechanism are submerged in oil so as to provide a thorough and constant lubrication, which protects the lubricating oil against contamination by grit, water, or other foreign substance.

Prime Movers and Their Accessories.

ROTARY VALVE.—G P B HOYT, 1 Clinton Place Jamaica, N Y, N Y In this case use is made of a cylindrical valve chamber having parts in its side and an opening in one end, a rotary valve fitting into said chamber and having a port adapted to register with said valve chamber ports, the said rotary valve being split at its port, and an annular partition fixed in the said valve chamber and having ports opposite the said valve chamber ports, the said partition being split intermediate its ports.

Pertaining to Recreation.

ILLUSORY THEATRICAL DEVICE FOR VAUDEVILLE ACTS.—H. J. MOORHOUSE, 335 W. 6th St., Superior, Wis. This invention relates to a stage appliance for use in a vaudeville act to produce an illusory or mystic effect, and it relates more particularly to a device adapted for use in connection with stereopticon, motion or other pictures. The illusion differs from all other attempts, by reason of the transformation taking effect under full white light, without the use of mirrors; and in the area of the picture screen containing only about 50 per cent of picture holding material, or two square feet of picture for each square foot of screen. The illusion is intermixed with acting, music, songs, animated scioptic posing effects and a mysterious fading away of the living image and shield.



DEVICE FOR VAUDEVILLE ACTS.

Railways and Their Accessories.

CHILD'S CRIB OR BERTH ATTACHMENT FOR RAILROAD CARS.—L. W. GEERKEY, Douglas, Ariz. In the present patent the invention is an improvement over that disclosed in Mr. Geerekey's patent, No. 1,055,897, dated March 11th, 1913, and it has reference to an improvement in the means for securing a crib to horizontal rails applied to the inner side of a railway carriage.

PNEUMATIC DERAILER.—J. J. MCINTYRE, care of D B Stauft, care of Taylor Coal & Coke Co., Uniontown, Pa. This invention contemplates positive means for derailing either loaded or empty trains or parts of trains, or "trips" of cars or mine wagons when operating on incline planes or slopes, in order to prevent serious wrecks when cars become detached through accident or otherwise. The invention provides for promptly derailing a runaway car or cars before the same attain a destructive momentum.

AUTOMATIC TRAIN STOP—J S ALLEN, 115 Broadway, New York, N. Y The stop has a hollow post, in which a shaft is journaled, a cap being secured to the shaft, and having depending lugs, which engage stops on the post for limiting the movement of the cap and shaft. The cap extends outward from the shaft, with means for protecting stops and lugs from the weather Secured to the cap is an extending arm engaged by a contact member, carried by arms secured to a shaft, journaled in a bearing on a locomotive or car with means that will rotate the shaft journaled in the bearing in the locomotive or car, to open the valve.

Pertaining to Vehicles.

WHEEL—J PEACE, Ogden, Utah. Address J G Heywood, same place. This invention relates to wheels, and more particularly to resilient treads An object is to construct a wheel in such a manner as to avoid the use of pneumatic tubes and casings, and yet produce a tread which will yield to an uneven surface so perfectly as to produce a pneumatic result.

Designs.

DESIGN FOR A RING OR SIMILAR ARTICLE—W. FISCHER, 45 John St., New York, N. Y In this gracefully rounded ring the setting comprises a number of prongs that clasp a high set disk, in the center of which the gem is placed.

NOTE.—Copies of any of these patents will be furnished by the SCIENTIFIC AMERICAN for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

We wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject matter involved, or of the specialized, technical, or scientific knowledge required therefor

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

MUNN & Co.,
Patent Solicitors,
361 Broadway,
New York, N. Y.

Branch Office:

Washington, D. C.

Notes and Queries

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12971) L. H. W. says: The original brightness can be restored to pearl articles by first cleaning them with pure olive oil. This penetrates the pearl object and does away with the blurred look Then polish as one polishes a finger nail Apply the polish and rub with a chamois skin.

(12972) L. H. W. Writes: Paint may be removed by the following mixture: One pound of commercial potassium hydroxide is dissolved in 40 ounces of acetone. Then add 20 ounces of methylated spirit, 20 ounces of oil of turpentine, 20 ounces of spirit of petroleum, and 10 ounces of castor oil. Wash off the paint with this mixture, using old rags to prevent mussing. If the paint is thick, a dull knife will aid materially in removing it, while no harm will be done to the wood if care if exercised.

(12973) H. J. G. asks: Will you be kind enough to tell me whether there are any detrimental effects incurred by the moving-picture operator, and if any, how caused? A. We know no reason why a moving-picture operator should be injured by his occupation more than any other man who works about electric lights. The eyes should not be exposed to the arc light directly at all, or certainly not for any length of time.

(12974) S. T. T. asks: In an argument recently with a railroad locomotive engineer, he declared that the top surface on the drive-wheels of an engine travels faster than the lower part of the wheels, but could not explain the fact If this is so, will you kindly send me an explanation? It seems a physical impossibility to me; however, it may be true A With reference to the motion of the parts of a wheel of a locomotive on the track, it must be evident to you upon thinking of it that the part of the wheel which is in contact with the rail at any moment is not moving forward at all, unless it is sliding on the rail, which you know it does not usually do. The top of the wheel is moving forward very rapidly. The bottom of the wheel is at rest on the rail, and the top is moving forward This your friend, the engineer, know, but could not explain It is not a physical impossibility, but a fact The wheel must not slip on the rail if it is to draw the train. If it does not slip, it is of course at rest on the rail at the point where it comes in contact with the rail.

(12975) S. C. S. asks: Inclosed find 10 cents for which send me copy of SCIENTIFIC AMERICAN that has the article in it in regard to making experiments with the *violet ray by using violet-colored glass*. If you can tell me where I could find anything else regarding this, I would like to know where it is A We send you under separate enclosure our SUPPLEMENT No 1920, containing a description of the various filters which have been used for separating the ultra-violet rays from the rest of the wave lengths of light. You can probably obtain the Wood ultra-violet ray filter directly from Prof R W Wood, Johns Hopkins University, Baltimore, Md We would advise that a violet-colored glass will not by itself quench all the rays except the ultra-violet A blue glass should be used with the violet glass for good effects. The choice of tints is also important It is better to get a glass made by a person of experience for first experiments Then you will know that you are producing what you should produce. Besides the SUPPLEMENT named above we have published many papers on this very interesting subject. We name the following: SCIENTIFIC AMERICAN, Vol 102, No. 12, Vol 107, No. 19; Vol 109, No 3, and SUPPLEMENT Nos. 1711, 1762, 1778, 1787, 1807, 1809, 1831, 1845, 1856, 1895, 1953, price, ten cents each.

(12976) D. L. W. asks: 1. I have read that water at 39 deg. Fahr. is heavier than at any other temperature Will you kindly explain why? A Water is densest at about 39 deg. Fahr and expands if either heated or cooled from that point. We do not know the reason why this is so, but it is of the greatest importance in nature. Because of this, ice forms on the surface of water instead of forming at the bottom of lakes and rivers and oceans 2. I have a toadstool which is petrified. Now that it has turned to stone, it is several times heavier than before. Will you kindly tell me where it got the additional weight? A. Your petrified toadstool weighs more than before petrifying because stone is heavier than the vegetable matter which was there formerly. 3 I have noticed more meteors fall to the southward than any other direction Is there any reason for this? A. We know no reason why you should have seen more meteors fall toward the south than toward any other point of the compass. Meteors enter the air from all directions and travel through it. 4. Will you kindly tell me if extremely cold weather will destroy the caterpillars in the brown-tail moth nests? A. The brown-tailed moth seems to get through the winters in the North in good numbers, so you might infer that it can endure the cold of our winter seasons.

NEW BOOKS, ETC.

A Day in the Moon. By the Abbé Th. Moreux. London: Hutchinson & Co., 1913.

The Abbé Moreux, whose contributions on astronomy have appeared in many of the better popular French magazines, has presented in this book a very readable account of the moon. To be sure, his day in the moon means not a twenty-four-hour terrestrial day, but fifteen terrestrial days, in other words, a lunar day. By carrying the reader in imagination to the moon, by exhibiting to him the great craters, mountain ranges, and vast expanses of frozen lava, the Abbé presents his facts in a very vivid way. The book is admirably illustrated. The translation may be commended as a good piece of work.

Handbuch für Heer und Flotte. Enzyklopädie der Kriegswissenschaften und verwandter Gebiete. Herausgegeben von Georg von Alten, Generalleutnant z. D., fortgeführt von Hans von Albert, Hauptmann a. D. Unter Mitwirkung von etwa 400 der bedeutendsten Fachautoritäten. Preis jeder Lieferung 2 M. – 2,40 K. Berlin W 57: Deutsches Verlagshaus Bong & Co.

The 65th, 66th, 67th and 68th installments of the "Handbuch für Heer und Flotte" take up from Kapudan-Pascha to Krasnoje Selo. The more important articles are those on *Karte, Kasematte, Kavallerie, Königgrätz, Kosten und Volkswirtschaftliche Wirkungen der Kriege*, and *Konstantinopel*. Major-General von Werlhof has written an excellent article on *Kasaken* (Cossacks) which bears the marks of much original research.

The Wanderings of Animals. By Hans Gadow, F.R.S. Cambridge: The University Press. New York: G. P. Putnam's Sons.

After tracing the rapid growth of this young science, the author shows how important is the subject of geographical distribution. The home is sketched, particularly the homes offered by tropical forests, deserts and high mountains, so that the various effects of climate and interdependence of animal and plant life may be brought out. Short chapters on the modes, means and rates of spreading show the effect of the natural increase in numbers, the relation of species numbers to individual numbers. How the map of the world has undergone many vast changes, and thus caused animals to readjust their home requirements, is simply indicated Especial portions of the book deal with the distribution of a considerable number of various groups of animals, mostly terrestrial vertebrates, selected for their fitness as test cases.

The Atmosphere. By A. J. Berry, M.A., Lecturer in Chemistry at Downing College. Cambridge: The University Press. New York: G. P. Putnam's Sons.

Meteorology plays no part in this book. Only chemical and physical phenomena are considered, Hence the book discusses the history of atmospheric study, gives a very good account of the principal constituents of the atmosphere. Briefly it reviews modern views on combustion and similar problems. The chapter on the escape of gases from planetary atmospheres according to the kinetic theory is particularly well done.

Primitive Animals. By Geoffrey Smith, M.A., Fellow of New College, Oxford. Cambridge: The University Press. New York: G. P. Putnam's Sons.

This little book well fulfills its object of presenting a simple account of modern views on the relationships of the chief groups of the animal kingdom, the principal grounds on which the modern classification of these groups may be justified, and an outline of the evidence by which some of the main streams of animal evolution can be traced.

Rocks and Their Origins. By Grenville A. J. Cole, Professor of Geology in the Royal College of Science for Ireland. Cambridge: The University Press. New York: G. P. Putnam's Sons.

This book is to be regarded as a companion to Mr. E. A N. Arber's "Natural History of Coal," also forming one of the Cambridge manuals of science and literature, for the author has omitted very wisely a discussion of those subjects which Mr. Arber had to take up Hence the author has not taken up the carbonaceous rocks, but he does give a very readable account of rocks in general, limestones, sandstones, clays, slates, igneous rocks and metamorphic rocks.

The Natural History of Coal. By E. A. Newell Arber, M.A. Cambridge: The University Press. New York: G. P. Putnam's Sons.

A more difficult subject than the geology or the palæobotany of coal could hardly be selected for popular discussion. Although coal is one of the most important substances in the world, still science has not yet determined what is the true origin of the material, how it was formed, etc. Hence the book before us is confined very largely to an elucidation of past and present theories.

Young Folk's Handbook. Philadelphia: American Institute of Child Life. 8vo.; 215 pp.; illustrated.

The After School Club represents an organized effort to guide boys and girls into happier and more educative and efficient ways of work and play. Its headquarters are at Philadelphia, but its scope is national, and it takes in young people of all ages. The members are graded, according to age, into "inner circles," each with its own particular interests and activities. The "Young Folk's Handbook" tells all about the club—what it is, what it is doing, how it does it, and why. The progressive sections of the book correspond with the ages dealt with—up to six years, from seven to fourteen years, and from fourteen to twenty-one years. Instruction is given in the exercise of the muscles, the development of regular habits, and the development of the imagination and the powers of expression. A large part of the work is devoted to a bibliography of suitable books, briefly reviewed. Parents and teachers will find both book and organization of immense value, and would do well to make them factors in the lives of their charges.

The Modern Locomotive. By C. Edgar Allen. Cambridge: The University Press, 1912.

The author has handled a very difficult subject with all the simplicity that can be expected. The general principles governing the design and working of a modern locomotive are clearly presented, and the broad lines of development from its comparatively simple predecessor of twenty-five or thirty years ago boldly traced. The thermodynamics of the locomotive engine play a very important part in the book, which is as it should be.

Aerial Locomotion. By E. H. Harper, M.A., and Allen Ferguson, B.Fc. With an Introduction by G. H. Bryan, Sc.D., F.R.S. Cambridge: The University Press. New York: G. P. Putnam's Sons.

Although since this book was written aerodynamic discoveries have been made, notably by Eiffel, which have markedly influenced aeroplane design, nevertheless the work may be recommended as a clearly worded account of the principles underlying the construction and behavior of aeroplanes and dirigibles.

The Physical Basis of Music. By Alexander Wood, M.A., D.Fc. Cambridge: The University Press. New York: G. P. Putnam's Sons, 1913.

An excellent, simply-worded presentation of modern theories of sound. In the space of only one hundred and sixty pages the author has managed to compress all that a well-educated man ought to know of sound and music.

Life in the Sea. By James Johnstone. Cambridge: The University Press. New York: G. P. Putnam's Sons.

Mr. Johnstone has written this popularly worded book on the basis of the German and Scandinavian studies of microscopic life contained in the sea. The German investigation, it will be remembered, was intended to determine the quantity of plankton; the object of the Scandinavian hydrographers was to forecast seasonal changes in the climatic conditions of their countries by studying the currents of the sea The researches conducted by these Germans and Scandinavians have had a marked influence upon marine biology and that influence is reflected in this book.

House Flies and How They Spread Disease. By C. P. G. Hewitt, D.Sc., Dominion Entomologist, Ottawa, Canada. Cambridge: The University Press. New York: G. P. Putnam's Sons.

This little volume will undoubtedly fulfill the hope of its author that it will not only bring home to a greater number of people the true nature of the house fly, but also indicate the means to be taken to eradicate it or render it no longer a menace. The author has done much work in investigating the structure, development and biology of the house fly and therefore writes from first-hand knowledge.

How to Build Up Furnace Efficiency. A Hand-book of Fuel Economy. By Jos. W. Hays. Chicago: Jos. W. Hays. 12mo.; 126 pp.; illustrated. Price, $1.

The writer compels attention from the start; tells you exactly why and how your fuel is being wasted, how to locate the point of waste, and how to stop it and keep it stopped. He is insistent that a full quarter of your coal is being needlessly wasted in burning, and engages to save you a quarter of your coal pile. Starting with the proposition that the most efficient furnace is the one which completely consumes the combustible with the least surplus of air, he shows how to diagnose trouble by the aid of the tallow candle, the flue gas analyser, the differential draft gage, and the pyrometer. His treatment is always popular, often humorous, sometimes whimsical, but it has the true stuff at the core of it, and it presents advice worth following and knowledge worth assimilating.

The Recent Evolution in Organ Building. Being an Account of Modern Developments. By George Laing Miller. New York: The Charles Francis Press, 1913. 12mo.; 192 pp.; illustrated. Price, $1 net.

The organ student will find in this work an illuminating presentation of organ history and of the men who have made that history. The papers are written primarily for the benefit of those who are concerned either in the purchase or the renovation of an organ, and specifications of many of the world's notable instruments are fully given. No organist should be without an understanding of the mechanical principles and the detailed construction of his instrument, and such knowledge is admirably supplied by the monograph in hand. The musical reputation of the author is international, and his qualifications for the task he has undertaken are indisputable

Motion Picture Making and Exhibiting. By John B. Rathbun. Chicago. Charles C. Thompson Company, 1914. 12mo.; 236 pp.; illustrated. Price, $1.

The field of the motion picture is steadily enlarging. From a mere amusement device it is coming to be utilized as a strong educational factor, and in other ways is demanding increasing respect and consideration. Mr. Rathbun's volume, while not so bulky as some similar works on the market, is clear and comprehensive, and demonstrates the author's fitness for the task of imparting his own wide knowledge. Early efforts in motography are reviewed, the modern projector and its accessories are described, and the film is shown in successive steps of its historical development. The actual picture taking is, of course, the subject of several lengthy sections, and the intimate details of studio arrangement and practice are revealed. The writer clearly explains the way in which certain trick films are produced. A portion of the work is also given over to the writing and marketing of scenarios That section of the volume dealing with the exhibition end of the business is quite as lucid and thorough as the chapters preceding, and contains instruction and suggestion that no theater manager can afford to ignore.

The Principles of the Application of Power to Road Transport. By H. E. Wimperis, M.A., M.I.E.E. New York: D. Van Nostrand Company, 1913. 12mo.; 130 pp.; illustrated. Price, $1.50 net.

The ever-increasing importance assumed by road transport carries with it a complication of problems toward which investigation and experiment are constantly leading to higher efficiency, both in the road itself and in the vehicle. Any consideration of resistance to motion on a road must deal with the primary factors of road-and-wheel friction, with the loss of power inherent in the mechanism and with the air resistance These factors are very thoroughly canvassed by the writer, and the most approved methods of determining their extent and of mitigating their drawbacks are explained. Their laws are reduced whenever possible to tables and formulæ Bench and road tests are described and the instruments and devices used are made the subject of illustration. Tractive resistance and friction curves are presented diagrammatically, the result of American experiments are tabulated and discussed; electric, internal combustion and hydraulic systems are subjected to investigation and analysis, and there are several useful appendices including reports on brake horsepower tests at Brooklands, road test report forms, etc. The work is a distinct addition to the somewhat scant literature of its subject.

L'Art de Reconnaitre les Fraudes. By M. Emile-Bayard (Inspecteur au Ministère des Beaux-Arts). Official of the Department of Beaux-Arts. Paris: Roger & Chernowitz. (99 Bd. Raspail.) In-18. 326 pp.; illustrated. Price, 5 francs; bound, 6 francs.

Owing to the experience which the writer has acquired by his long connection with the State Beaux-Arts department, he is well qualified to treat such subjects as the present, and the result is an interesting volume about the various kinds of frauds which are now so largely practised in the production and sale of works of art, antiquities and bric-à-brac He points out the fact that the public is largely responsible for this state of affairs owing to the heavy demand for all kinds of antiquities that is made at present, and this is surely on the increase, so that antiquity itself would not have had the time to produce them. As a natural result, skill in producing "ancient" objects is increasing to keep pace with the demand, and the already great quantity of objects turned out is not likely to diminish. Paris is, of course, one of the centers of the industry. M. Emile-Bayard passes in review the classes such as painting sculpture, old furniture, metal and ivory objects, ceramics and tissues, so that amateurs will be aided in detecting at least certain kinds of frauds though in higher class work the skill in imitating antique objects often baffles even the expert The author has chosen to enliven the book by the use of a literary style which we should have preferred to take for granted, and a condensation of the same would have allowed of devoting more of the work to positive data or at least of anecdotes and local color. Numerous photographs, over a hundred in fact, add much to the value of the book, and it is certainly a welcome contribution to this little-known subject.

Col. J. M. Schoonmaker and the Pittsburgh & Lake Erie Railroad. A Study of Personality and Ideals. By Harrington Emerson. New York: The Engineering Magazine Company, 1913.

As Mr. Emerson developed and applied the principles of efficiency engineering—a profession at the head of which he now stands—the importance of the human element grew upon him He realizes, now, as perhaps very few efficiency engineers do, that while machines may be arranged most effectively, while they may be supplied with material rapidly, while factory buildings themselves may be models in their way, ultimately the man behind the machine must be regarded as the hub of every great manufacturing enterprise. Curiously enough, everything in a modern industrial organization seems to have been closely studied except the human beings upon which its ultimate success is dependent. Hours, days, weeks, and even months may be devoted to a painstaking study of mechanical equipment, but not ten minutes to the men who will be charged with the operation and maintenance of that equipment Mr Emerson was one of the first to insist upon the same care in the selection of human as of mechanical material His later writings have dwelt eloquently upon the necessity of studying a man's aptitudes before entrusting him with work, however important or unimportant He has set up certain human standards and ideals which correspond with the standards and ideals to be followed in selecting and arranging the machines of a factory Human characteristics mean as much to him as heat units to a mechanical engineer

In this remarkable study of Col J M. Schoonmaker, to whom the amazing success of the Pittsburgh & Lake Erie Railroad is due, Mr Emerson has crystallized his vast experience with humanity, and applied his human standards to a great personality In many ways, the study of Col J M Schoonmaker as a man as a soldier and as an executive, is the most eloquent piece of writing that Mr. Emerson has thus far given to the public, which is saying much when it is remembered that Mr. Emerson has a highly developed literary sense, that he writes with a grace that comes from wide and appreciative reading, and that he drives home an argument with many a striking historical simile In the first half of this book there are more quotable passages than are to be found in a whole volume of most modern essays. This study of Col. J M Schoonmaker as a personality and as an executive might be read with profit by every manager great or small. It is inspiring as well as instructive.

Plant-Life on Land, Considered in Some of Its Biological Aspects. By F. O. Bower, Regius Professor of Botany in the University of Glasgow. Cambridge: The University Press. New York: G. P. Putnam's Sons.

"Few pursuits are more thoroughly misunderstood by the average person of education than that of the present-day botanist . . . Old, time-worn aspects of the science are assumed still to be living problems of the day In no point does this emerge more clearly than in the undue importance attributed to the finding and recording of new species and varieties This is a survival of the time when the science, still in its infancy, was mainly engaged in the recognition and tabulation of living forms" Thus Prof Bower opens his interesting, popularly written book, and prepares the reader for the modern view of botany When the reader who clings to the old-fashioned view has finished this book, he will probably discard the notion that modern botany consists entirely in finding and recording new species and varieties and that a botanist's ability is to be measured by the number of the new determinations He learns that the modern botanist concerns himself not simply with plants as they are, but inquires into their origin, their stability as species, and their relations with one another.

Numbers in History. How the Greeks defeated the Persians, the Romans conquered the World, the Teutons overthrew the Norman Empire, and William the Norman took possession of England. Two lectures delivered before the University of London on October 6th and 7th, 1913, by Dr. Hans Delbrueck, Professor of History of the University of Berlin. London: University of London Press Published for the University of London Press, Ltd, by Hodder & Stoughton, 1913

The critical study of the four great campaigns which form the subjects of those lectures serve to overthrow some deep-rooted ideas The "hosts" of old were anything but hosts as we conceive the term What is more, the great captains of the past seem to have lied about their commands as glibly as tradition itself Instead of overcoming 80,000 Austrians and Sardinians with a handful of 30,000 French, as he claimed, Napoleon was able to oppose 40,000 against 47,000

The mere difficulty of handling large armies—a difficulty which could hardly be overcome before the days of the railroad—speaks eloquently against such vast bodies as the ancients sometimes claim to have hurled against their enemies Even with the aid of nine railways and good roads, Von Moltke found it hard to move 400,000 men. Indeed, at Vionville, he could only use two of his ten army corps Again, the mere task of provisioning an army of 100,000 or 200,000 is in itself something that the ancients could hardly have coped with No wonder that Prof Delbrueck doubts that Attila led 700,000 men from Germany over the Rhine into France, and no wonder that he doubts Herodotus's statement that Xerxes marched westward at the head of 5,100,000, for at that rate, the last man would have just about left Susa when the first arrived before Thermopylæ Dr Delbrueck even goes so far as to maintain that the Persians were outnumbered by the Greeks. "Why should the Greeks have more credibility? Are we to believe them only because we have no Persian author who contradicts their stories?" So, too, he questions whether Charles the Bold was able to oppose 100,000 men against the Swiss, and even goes so far as to maintain that the Burgundians were outnumbered by the Swiss. The invasion of the 200,000 Cimbri of the Roman histories becomes an invasion of no more than 40,000 people, of whom 10,000 were soldiers. Why? Because only that number could have migrated at once across the Alps So the army of William the Conqueror is reduced from 60,000 to 7,000, and that of Harold to 4,000.

Will You believe John Burroughs?

READ this letter from America's greatest living naturalist—one of the many hundreds written by distinguished authors, statesmen, clergymen and scientists who have wished to tell the world what the food-tonic Sanatogen has done for them. These letters have the ring of sincerity because they are the grateful letters of active workers in many professions who, after suffering the strain of nervous exhaustion, have felt the lifting, nourishing, *reconstructive* influence of Sanatogen.

Even more impressive are the letters from over 19,000 practicing physicians—conservative scientific men who have prescribed Sanatogen and, watching its effects in rebuilding and strengthening men and women who were "run down," have with this full knowledge praised its power to help.

Should *you* not believe that this help for which so many of the world's active workers are grateful may be a blessing to you?

Sanatogen is sold by good druggists everywhere, in three sizes, from $1.00.

Mr. Burroughs writes:

"I am sure I have been greatly benefitted by Sanatogen. My sleep is 50 percent. better than it was one year ago, and my mind and strength are much improved."

Send for Elbert Hubbard's new book—"Health in the Making." Written in his attractive manner and filled with his shrewd philosophy together with capital advice on Sanatogen, health and contentment. It is free.

THE BAUER CHEMICAL CO., 28G Irving Pl., New York

Grand Prize, International Congress of Medicine, London, 1913

The "BEST" LIGHT

Used in every civilized country on earth. Best and cheapest light for homes, stores, factories and public buildings. Makes you independent of lighting companies. Over 200 styles. Every lamp warranted. Makes and burns its own gas. 100 to 2,000 candle-power. Agents wanted. Write to-day for catalogue and prices.

THE BEST LIGHT CO.
87 East 5th Street,
Canton, O.

2¢ a week

No Dirt
No Grease
No Odor

WATERMAN "PORTO" MOTOR

2½ to 3 H.P.
Weight 59 lbs.

Makes any Boat a Motor Boat

The original outboard motor. 9th year—25,000 in use. Guaranteed for life. Fits any shaped stern. Drives rowboat 8 miles an hour on quart of gasoline.

BUY DIRECT FROM FACTORY
Freight Paid. Save Agent's Profit

Insist upon getting these essentials: *Carbureter*, not "mixing valve"; *3 Piston Rings*, *Removable* Phosphor Bronze Bearings; Bronze Skeg; 10½ x 16" Propeller, Rudder, Noiseless, Underwater Exhaust, Spun Copper Water Jacket, highly polished.

Postal brings Free Engine Book.

Protection from X-rays in Radiography

(Concluded from page 310.)

volume. In certain types of tube, therefore, the platinum anticathode gets red-hot at times, a circumstance which does not cause serious inconvenience with such low current volumes.

When, however, it is desired to employ higher energies in X-ray tubes, this elevation of temperature becomes the source of great annoyance in the operation of the tube and renders its construction very difficult. Here are the reasons: the center of emission of the X-rays is situated in the interior of a closed space in which the most careful vacuum has been made. This reduces very materially thermic radiation, so that, while the output of energy constantly raises the temperature of the anticathode there is but little tendency to heat-loss.

We must also take into consideration the fact that, at the Cochin Hospital, as in nearly all large installations, X-ray tubes are used with a capacity for current equivalent to 4 or 5 electrical horse-power. This energy is almost entirely concentrated in the cathode stream and, consequently, absorbed by the anticathode which reaches a white-hot temperature instantaneously. In order to avoid, as much as possible, this inconvenience, the anticathode is reinforced and constructed of the most refractory metals such as platinum, iridium, and tungsten.

It is also found likewise advantageous, especially when the exposure is to last several seconds, to employ accessory cooling, produced either by a volume of water stored behind the anticathode or by the passage of an air jet of high velocity (Barret-Jaiffe system), which removes with it a great quantity of calories.

Finally, in conjunction with the radiologic installation just described, we find, in this new clinic of the Cochin Hospital, apparatus for the use of high frequency currents,* a remarkably well equipped laboratory in the basement, and a collection of more than 25,000 radiographic negatives of considerable documentary interest.

Vocational Guidance and Efficiency

(Concluded from page 312.)

and economic—of these children; it shows itself also in the lives of the children that it manages to retain, for the majority of these are *not* going to be professional workers, and the school neither prepares them for anything else nor lets them even know that there is anything else. Vocational guidance will necessitate an organization and an administration of schools that will make it possible for the children's native abilities to assert themselves and to record themselves, that they may be utilized in planning each individual's school career in accordance with his particular needs, and not in accordance with a remote and arbitrary standard set up a few generations back by men interested in the evolution of grammatical inflection or Roman table manners.

Modern psychology, resting upon a biological foundation, has shown us the facts of individual variation in a new light. Plato recognized that all men were not equal, and he assigned the various functions in his Republic to classes of people manifesting special traits of character. The assumption of most philosophers who have thought about the distribution of human services in accordance with native talents has been that each person is naturally fitted to some particular place in the social and economic fabric; they have accordingly sought some scheme for discovering the earmarks of the scavenger and of the soldier. The newer studies of human nature show us that there are indeed individuals who are "natural born" poets or painters or hostlers or fishermen; but that the tremendous majority of boys and girls can be roughly divided into a few large groups, and that within each group by far the largest number of individuals are capable of adjusting themselves to a great variety of occupations. We can distinguish roughly between those who have a high degree of mathematical ability, those who have a low degree of it, and those who have a medium capacity for quantitative thinking. But we cannot direct all in the first group into astronomy or molecular physics; nor can we direct all in the last group away from engineering. We may say to a boy who is color-blind that he cannot become a locomotive engineer or a pilot or a sign painter, but color-blindness did not prevent Dalton from becoming a tolerably good chemist.

When it comes to discovering a child endowed with some talents in a high degree, or to encouraging a genius, we do not need "vocational guidance." We need some machinery for discovering mediocre talents in every-day girls and boys, some opportunity for developing these talents, some way of connecting them up with the useful work that is going on around us—that need it is that seeks to express itself through the vocational guidance movement. That the meeting of this need will help industry and commerce should bring the far-sighted business man to the assistance of the movement. That the meeting of this need will help put life and enthusiasm into the schools should bring all educators to its assistance. That the increased efficiency resulting from organized common sense applied to the direction of girls and boys will be both civic and economic, ought to interest the statesman.

Nebuchadnezzar as a Builder

(Concluded from page 314.)

I caused to be more magnificent than before, I did as I was instructed. All my noble deeds for the maintenance of the sacred temples of the great gods, which I did better than the kings, my fathers, I wrote upon a tablet of stone, and fixed for distant days.

"May the wise men after me read of all my works which I have written upon a tablet. May they comprehend the glory of the gods. I accomplished the building of the cities of the gods and goddesses, as Marduk the great lord bade me, and urged my heart to undertake.

"In those days, for Ninharrak, my beloved mistress, who guards my life and gives me good dreams, I dug up and found the ancient foundation of Eharsagil, her temple in Babylon, which fell to ruins in ancient days, and no previous ruler had restored. . . . But the temple was not suitable for the abode of Ninharrak. To strengthen the walls of that temple, and of mortar and bricks to make a temple worthy of Ninharrak, I sought earnestly. Upon the day when I asked the gods to reveal to me the future, Ramman and Shamask decreed that I make three burned bricks of sixteen fingerbreadths in size, and to make an image of burned clay as a charm against disease. And so I made three burned bricks of sixteen fingerbreadths and an image of baked clay to drive away disease, and I placed it in the foundation. With mortar and burned bricks I erected the main temple mountain high.

"O Ninharrak, majestic mistress, when with joy thou enterest Eharsagil, the house of thy pleasure, may words in my favor be ever upon thy lips. Make long my days and establish my years, may long life and an abundance of offspring be decreed by thy lips. Give peace to my soul; make my body strong, and make my visions clear. With Marduk, the lord of heaven, command the destruction of my foes, and the ruin of the land of my enemies.

"In those days, in the temple of Lugal-Marada, my lord, in Marada, whose ancient foundation no former king had seen since the days of old, I sought its ancient foundation and found it, and upon the foundation of Naram-Sin, the king, my ancient ancestor, I fixed its foundation. I made an inscription with my name, and placed it there.

"O Lugal-Marad, lord of all, hero, kindly look with favor upon the work of my hands. Grant as a gift a life of many days, an abundance of posterity, security to the throne, and a long reign. [illegible]

* High frequency currents are used in the treatment of arterio-sclerosis, alleviation of rheumatoid and neuritic pains, the treatment of neurasthenic conditions and the like.—Editor.

Fill your factory with sunshine

Buy it by the barrel and let it penetrate into every corner of your plant. It will give you 19 to 36 per cent more light than you had before. It will lengthen your daylight day, cut down your lighting bills, improve sanitary conditions. Paint your ceilings and walls with

RICE'S MILL WHITE

The only oil paint (without varnish) giving a glossy, tile-like finish

It will fill your factory with sunshine. It will reflect every ray of your natural or artificial light down on your machinery and into the dark corners of your plant. Its glossy surface will not absorb light or collect dirt, germs and odors like a flat paint. It can be washed like tile.

Rice's Mill White will not scale and require frequent renewals like a cold-water paint. It will not "alligator" and crack under the jar of machinery like a varnish paint. It flows easily under a 4" brush; two coats equal three of lead and oil. *It stays white longer than any other gloss paint.*

The Original Mill White

Rice's Mill White made a trade name of the words, "Mill White." There is no substitute for it. None of its imitations has its elastic, permanent qualities. No other paint manufacturer can use the Rice process. Rice's Mill White for ten years has proved itself unequalled for illuminating power, sanitary qualities and low ultimate cost.

Rice's Mill White is sold direct from our factory, in barrels containing sufficient paint to cover 20,000 square feet, one coat. If you have that area of ceiling and wall space to cover,

Write for Booklet and Sample Board

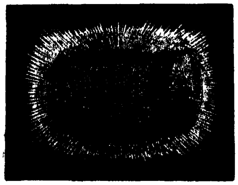
Ask for a copy of our booklet "More Light." WRITE TODAY

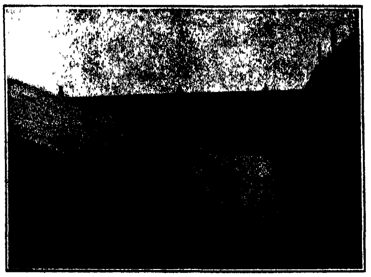
U. S. GUTTA PERCHA PAINT CO.
No. 23 Dudley Street PROVIDENCE, R. I.

Rice's Granolith

A tough and elastic, permanent finish for concrete walls. Becomes a part of the cement to which it is applied. One coat sufficient, unless a gloss is desired. Makes the best possible primer on inside concrete and brick for a second coat of Rice's Mill White Paint, giving a tile-like, enamel finish at no more expense than lead and oil paint.

For Concrete Surfaces





Build Better, Quicker, at Less Expense

Of concrete, certainly, even to the roof, but of concrete reinforced with the new form of expanded metal that cuts out the expense and time delay of building forms.

(Pat. Mar. 3, 1914. Other patents pending)

makes possible a roof of concrete but two inches thick—a roof of any shape, fireproof, light, but as strong and enduring as one made in the old way twice as thick.

Self-Sentering makes unnecessary, too, all studding on walls and partitions—saves inches in partition thickness that add square feet to every floor area

Laid quickly in big sheets, it makes permanent building construction quicker and more economical.

Your architect and builder know the advantages of Self-Sentering. *You* ought to know more about it before you build. If you will

Send Us Your Architect's or Builder's Name

we will supply you with full information regarding this economical method of concrete construction

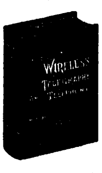
WIRELESS TELEGRAPHY AND TELEPHONY
SIMPLY EXPLAINED
By ALFRED P. MORGAN, Wireless Expert

170 Pages, 156 Illustrations, Cloth Bound

Price, **$1.00** postpaid

The simplest, latest and most comprehensive popular work published on wireless, for the wireless operator, amateur or professional.



THIS is a comprehensive treatise and a close study of its pages will enable one to master all the details of the wireless transmission of messages. The author has filled a long-felt want and has succeeded in furnishing a lucid, comprehensible explanation in simple language of the theory and practice of wireless telegraphy and telephony.

The book treats the subject from an entirely new standpoint. Several very novel and original ideas have been carried out in its making. It is well illustrated by over one hundred and fifty interesting photographs and drawings. All diagrams have been made in perspective showing the instruments as they actually appear in practice. The drawings are carefully keyed and labeled. Many of the photographs are accompanied by phantom drawings which reveal the name and purpose of each part.

This is a book the wireless experimenter cannot afford to be without. It enables one to design and construct their own apparatus. This book will also prove of value to the layman.

the evil minded; break their weapons; devastate the lands of my enemies. Slay all of them. May thy fearful weapons which spare not the foe be stretched forth, and be sharp for the defeat of my enemies. May they be at my side. Before Marduk, lord of heaven and earth, make my deeds appear acceptable; intercede for me."

How the Moving Picture Machine Was Made Safe

(Concluded from page 315.)

zine is set in a recess in the main frame of the picture machine. The magazine doors are of full size and hinged to swing open. Spring hinges are used so that the doors will not stand open.

The film is most likely to ignite in the machine mechanism between the upper and lower magazines. There, too, is the projection aperture where the light rays are condensed upon the film. Immediately following the development of the flame-proof film magazine, Mr. Power devised an automatic shutter to cover the aperture and cut off the light when the machine stopped.

The improved form of fire shutter for projection apertures *S* (Fig. 6) is controlled by the speed of the film. It does not open until the film attains a certain speed and closes when the film slows down and before motion actually ceases. The operating mechanism consists of a centrifugal clutch and lifting lever. The clutch revolves when the film moves, and when proper exhibiting speed is attained it operates and moves the lever, which raises the fire shutter, so that the light rays are free to enter the aperture. The shutter is hinged laterally and drops by gravity into a normal closed position.

That portion of the machine-head mechanism of a motion-picture projecting machine which holds the film flat as it is rapidly jerked over the aperture by the intermittent motion is termed a "film trap" or "gate." One of the first things Nicholas Power did was to construct film gates so that films would not burn beyond them when ignited in the aperture. And so snug do these fit that even the sprocket hole margins of films are not burned when films ignite

As the metal surrounding the aperture is heated to a high degree by the condensed light from the lamp and likely to ignite slivers of film which sometimes cling to the parts, Mr. Power set out to minimize the possibility of these slivers igniting and firing the film by arranging a "cooling plate" over the film gate. This plate is set away from the gate about one quarter of an inch and absorbs and radiates the heat from the light On this plate the fire shutter *S* (Fig 6) is mounted.

Having protected the film at the most hazardous point, Mr Power anticipated the necessity for protecting the film above and below the aperture The first step was a flame shield of metal above the aperture to protect the film from fire below The original form has been improved. In recent machines the upper shield *U* (Figs. 6 and 5) is a semi-circular trough of sheet metal, hinged at the bottom, through which the upper loop of film travels.

Next followed a shield below the aperture. This shield was improved from time to time until it formed a complete enclosure about the loop of film below the aperture *L* (Figs. 6 and 5). This form of lower film shield shown in these figures swings open at the side Attached to it is a guard plate *G* (Fig. 5), which arrests the rays of light from the lamp when the shield is thrown open and guards the film from accidental ignition should the operator be careless in handling the films.

Having minimized the possibilities of accidental ignition of the film, Mr. Power turned his attention to improvements in the operating mechanism of the film. One of the most important of these is the automatic loop setter which prevents the loss of the necessary loop in the film between the aperture and the take-up reel. As the film travels past the aperture in rapidly successive jerks a direct pull from the take-up reel would break it. When a film

LEGAL NOTICES

PATENTS

If you have an invention which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of more than sixty years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to PATENTS, TRADE MARKS, FOREIGN PATENTS, etc.

All patents secured through us are described without cost to the patentee in the SCIENTIFIC AMERICAN.

NEW YORK UNIVERSITY
SCHOOL OF APPLIED SCIENCE

offers to graduates of approved high schools four-year courses leading to the degrees of Bachelor of Science in Civil Engineering, in Mechanical Engineering and in Chemical Engineering.

Bulletin upon application to
[illegible]

Would you be President for $25,000 a Year?

From a hundred million voices we hear a unanimous assent.

Strange how many of us are willing to show our ability in that line! No doubt some of us would be willing to take the job and pay the salary ourselves.

And that doesn't mean that $75,000 is too much for the men who have really occupied the big chair. Not a bit! But you know there was a time (before prices went up) when we only paid our presidents $25,000 a year. In 1873 we gave them their first raise.

That was two years after Richmond Straight Cuts raised a new standard for the smokers of our country. Many cigarettes have come and gone since then and are forgotten.

That Richmond Straight Cuts continue to hold the title they won so long ago—Best of all Virginia* Cigarettes—is due to their unwavering quality. Truly they have *lived* up to a high standard.

Besides the regular package of 20, these cigarettes are also packed in attractive tin boxes, convenient for den, office or traveling, 50 for 40c; 100 for 75c. These larger packages will be sent prepaid on receipt of price, if your dealer cannot supply them

breaks this way it continues to feed down from above, and oftentimes ignites in the aperture before the operator can stop the machine. The loss of this lower loop has been a common fault. It is caused in a number of ways—defective sprocket holes in the film, too much tension in the take-up, and the like. But no matter what the cause is, and even when highly mutilated films are run through the machine, the setter automatically adjusts the loop without let or hindrance on the part of the operator, every time it slips. Should the operator desire to set a fresh loop the lever *O* (Figs. 6 and 5) is depressed.

It is not generally understood that each picture on the film must stop over the aperture, but only for a minute fraction of a second. This is the foundation principle of kinematography. The mechanism that controls the stopping and starting of the film, the intermittent movement, must move the film during the period of travel as quickly as possible and allow the longest possible periods of rest, and do this without straining the film. Some years ago Mr. Power realized that the common star-wheel and geneva intermittent movement was not susceptible of further development and forthwith developed the cam and cross intermittent movement. This movement is one of Mr. Power's most signal inventions. It moves the film faster than the star and geneva possibly can, and increases the period of rest. And these operations are accomplished with far less strains and whip-lash pulls so common in the other movements. The film is not jerked from rest and does not attain full speed until the middle of the period of travel. This movement is one of Mr Power's safety features, as it handles weak and poorly patched films without rupturing them, and every film that breaks means a potential fire. Moreover, this movement has eliminated the painful flicker so common in old mechanisms and increased the safety to the eyes of the public.

For these inventions Nicholas Power was awarded a gold medal at the International Exposition of Safety, which was held under the auspices of the American Museum of Safety in New York, December, 1913.

Popular Beliefs and Scientific Facts

POPULAR beliefs on scientific subjects apparently run in waves. Many of our readers remember the interest in hypnotism which followed the publication of "Trilby." Svengali with his "hypnotic eye" at once became a real and possible personage in the public imagination. The newspapers were full of stories of girls and women who had suddenly been fixed and paralyzed by the hypnotic gaze of some mysterious stranger with piercing black eyes, and who had been compelled by his will to fantastic acts which they were powerless to prevent. Fiction writers took up the idea, and stories centering around hypnotic influence became common. It was used as a plea in criminal cases, various culprits alleging that they had been hypnotized and compelled against their will to perform unlawful acts. All this occurred in spite of the fact, frequently stated and known by every scientific man, that the limitations of hypnotism are definite and well recognized, that no person can be hypnotized unknowingly or against his will, and that few persons are so susceptible as to be capable of being compelled to perform acts beyond their own volition and knowledge.

Another popular fiction which later on took the place of hypnotism was that of instantaneous anesthesia. Stories appeared in the newspapers of women who had been accosted by strangers and, under some pretext, had permitted a cloth or a handkerchief to be pressed momentarily over their mouth and nose. Immediate unconsciousness was said to have followed, resulting in a period of insensibility and irresponsibility, varying from a few minutes to hours or even days. Chloroform sprayed into an open window by means of an atomizer, anesthetics tied to a rag on the end of a pole and thrown into a bedroom, instant unconsciousness following the administration of drugs unknown

We have just issued a new catalogue of scientific and technical books, which contains the titles and descriptions of 3500 of the latest and best books published, covering the various branches of the arts, sciences and industries. Our Book Department can supply these books, postpaid, at the regular advertised price.

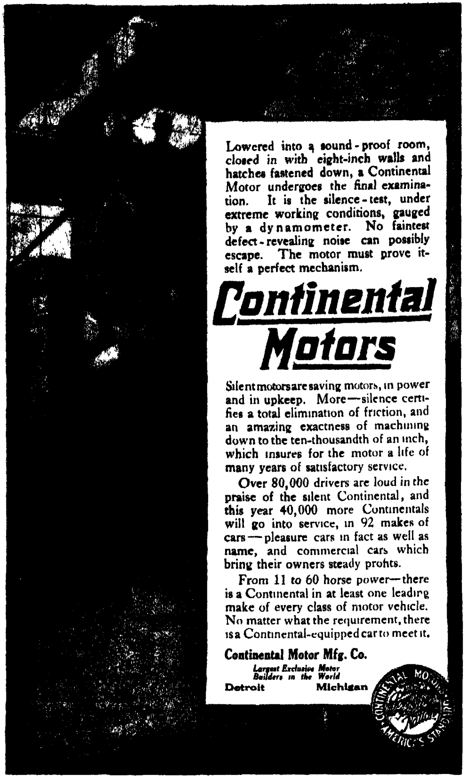
Sears, Roebuck and Co., Chicago



Lowered into a sound-proof room, closed in with eight-inch walls and hatches fastened down, a Continental Motor undergoes the final examination. It is the silence-test, under extreme working conditions, gauged by a dynamometer. No faintest defect-revealing noise can possibly escape. The motor must prove itself a perfect mechanism.

Continental Motors

Silent motors are saving motors, in power and in upkeep. More—silence certifies a total elimination of friction, and an amazing exactness of machining down to the ten-thousandth of an inch, which insures for the motor a life of many years of satisfactory service.

Over 80,000 drivers are loud in the praise of the silent Continental, and this year 40,000 more Continentals will go into service, in 92 makes of cars—pleasure cars in fact as well as name, and commercial cars which bring their owners steady profits.

From 11 to 60 horse power—there is a Continental in at least one leading make of every class of motor vehicle. No matter what the requirement, there is a Continental-equipped car to meet it.

Soldering and Brazing

for nearly all metals, including such difficult ones as cast iron and aluminum, have been the subjects of hundreds of paragraphs in the Scientific American Supplement. We quote a few of the more important articles, as follows:

Scientific American Supplement No. 1673—*Full instruction for Mending or Welding Cast Iron*, gives both brazing solders and fluxes necessary

Scientific American Supplement No. 1713—*Brazing Cast Iron and Other Metals*, gives detailed instructions for the whole operation, and formulas

Scientific American Supplement No. 1644—*Soldering and Soldering Processes*, gives broad general information, and contains in particular a method for pulverizing solders and alloys of great use

Scientific American Supplement No. 1667—*Some Soldering Appliances*, describes the blowpipe and the furnace in their various forms

Scientific American Supplement No. 1481—*Soldering of Metals and Preparation of Solders* gives many formulas for soft and hard solders and fluxes

Scientific American Supplement Nos. 1610, 1622, 1626 contains a series of three articles on Solders, covering the entire range of solders for all metals No 1628 contains formulas and instructions for *soldering aluminium*

FOR 80 cents—the price of the eight numbers postpaid, the purchaser of these Supplements has a complete treatise on the subject of Soldering and Brazing, containing formulas of the greatest value

EACH number of the Scientific American or the Supplement costs 10 cents A set of papers containing all the articles here mentioned will be mailed for 80 cents Send for a copy of the 1910 Supplement Catalogue, free to any address Order from your newsdealer or the publishers

MUNN & COMPANY, Inc., 361 Broadway, New York City

to physicians and pharmacists, were some of the variations of this idea. In the minds of physicians and nurses who see every day the administration of anesthetics, such stories only excite mirth. Any one who knows the difficulty and labor of securing unconsciousness through the use of anesthetics, even under the most favorable conditions and with every possible means for restraining and controlling the patient, knows how absurd such stories are—*Journal of the American Medical Association.*

A Rockefeller Fund for the Study of Animal Disease

IT is announced that John D. Rockefeller, through the General Education Board, has added $1,000,000 to the endowment fund of the Rockefeller Institute for Medical Research, for the establishment of a department for the study of animal diseases, and that James J. Hill had given $50,000 to be devoted to the study of the disease known as hog cholera.

The ravages of diseases among animals have not only endangered the health of human beings, but have cost the country many millions of dollars. They are one of the factors in keeping up the "high cost of living."

In the history of medical science the work of Pasteur on anthrax and the more recent observations in this country on Texas fever in cattle, which opened the door to present knowledge concerning insect carriers of malaria, yellow fever and other diseases, are conspicuous illustrations of the value of studies on animal diseases.

How imporant the work promises to be would follow from statistics issued by the Rockefeller Institute It has been estimated that in the Northwest alone hog cholera has killed $60,000,000 worth of swine during the last year.

Significant evidence of the importance of such investigations as the new department will undertake and of the expediency of undertaking them in the manner proposed is to be found in the fact that a contribution of $50,000 to aid in the study of hog cholera has been received from James J Hill

With the present facilities at hand, the income from the $1,000,000 endowment will make it possible to carry on the work on a broad scope at once.

A Legislative Reference Bureau for Congress

THE latest annual report of the Librarian of Congress devotes much space to the proposal embodied in recent bills before Congress to establish a legislative reference bureau, the functions of which would be to collect data bearing on proposed legislation and furnish expert assistance in the drafting of bills The utility of such a bureau, not only as a means of preventing downright blunders in legislation or serious defects and ambiguities in the language of bills, but also of facilitating the work of legislators, is obvious to everybody who has given the matter any attention, and has, moreover, been demonstrated by the experience of about twenty State legislatures which have already adopted a plan of this character. It is proposed to make the Congressional legislative bureau a branch of the Library of Congress.

Herschel Island Police Post Abandoned

IT is reported that this winter, for the first time in many years, the Canadian Northwest mounted police have been obliged to abandon the lonely outpost which the Dominion government maintains, at a cost of over $100,000 a year, on Herschel Island, in the Arctic Ocean, for the purpose of collecting duties from American whalers and prospectors, keeping order among the Eskimos, and assuring Canadian sovereignty in the far North. This action is due to the fact that the steamer bringing supplies from Nome was unable to reach the post on account of storms and ice floes, and may add to the perils of several vessels, including part of Steffinsson's expedition, supposed to be icebound in that vicinity.

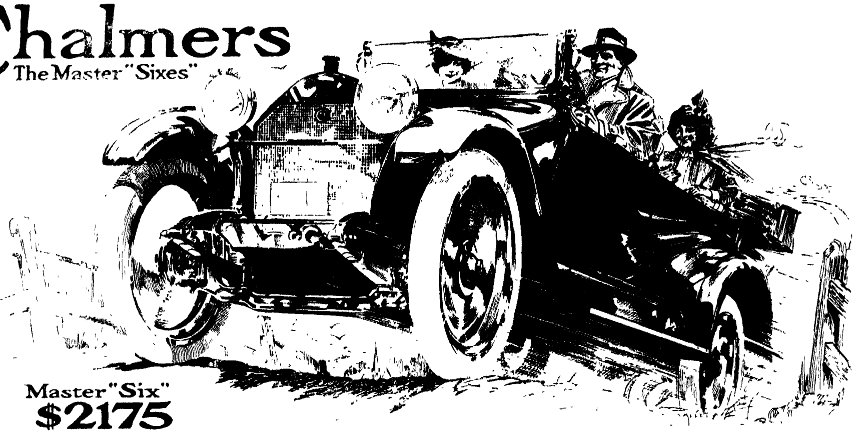
The Master "Sixes"



Master "Six"

$2175

6-passenger Touring Car, $2275

$10,500,000 Worth of Evidence

The combined salaries of all the Presidents from George Washington to Woodrow Wilson would buy only one-third the Master "Sixes" now in use, $10,500,000 worth. Many of these cars have been driven thousands of miles. 61% of their owners abandoned other cars when they bought Master "Sixes," so they can make comparisons—can speak from experience.

Through these men the fame of the Master "Six" has spread like wild fire. In all sections sales have far outstripped all past records. For unconsciously every Master "Six" owner becomes a Chalmers salesman. Even we did not foresee the nation-wide triumph of the Master "Six," so we will run short at least a thousand cars this season, that's certain.

The Man Who Knows

Men bought Master "Sixes" not upon impulse but upon positive knowledge.

Do as these men did, talk with those who own Master "Sixes." They will tell you first, that the resistless sweep of the "Six" is not founded upon a fad, but upon these logical reasons silence, smoothness and flexibility. They will tell you that these advantages are so real in the Master "Six" that they are forever spoiled for any other car.

You may still think of a "Six" as necessarily a heavy car, costly to buy and expensive to keep. Once that was true. But that day passed with the coming of the Master "Six."

What Owners Have Found Out

Owners will tell you that it is heavy enough for the utmost in safety and comfort, yet light enough to be easy on tires and frugal with fuel, that the continuous power of its six cylinders has done away with vibration, and so reduces wear and tear almost to nothing.

Former owners of high priced cars have learned that in the Master "Six" they secure the same six-cylinder luxury without the usual six-cylinder expense.

Get the Evidence Yourself

Among the thousands of owners of Master "Sixes," some live in your vicinity. Ask us, or your dealer who these men are. Talk to them. They can give you facts it would be folly to ignore.

Then let our dealer take you on the Chalmers Test Ride. See with your own eyes the beauty of its streamline body. Feel with your own hands the ready response of its supple power. Learn the charm of its luxurious silence and comfort. Then it will be plain why, in half a year, men have paid over ten millions for the Master "Six."

A Master "Light Six"—$1,800

No longer need those who want six-cylinder luxury, hold back on account of the price. Here's the Master "Six" built on a lighter scale; with the same motor but a smaller and lighter model; yet it shows 30 to 50 horse power and has more speed than you'll ever need.

Light for the sake of economy in tires and fuel; yet with a 126" wheel base for roomy comfort. Graceful in outline, distinguished in appearance; and sold at a price which sweeps away the last reason for doing without a "Six."

A Princely Inheritance

This lighter "Six" has all the features which have made the Master "Six" illustrious.

Its small bore and long stroke motor give it the same flexible power—from a snail's pace to an express train speed without shifting gears.

The steady pull of its six cylinders gives smoothness of motion, resistless in its charm; a smoothness that cuts wear and tear to the vanishing point. Its lighter weight means added economy in fuel and tires, while its price makes it easy for multitudes to own "Sixes."

Strength No Longer Means Weight

Time was when "Sixes" were heavy to secure comfort and the required margin of safety. So now one marvels at the sturdy strength of the Master "Light Six."

This is due to the simplicity of the Chalmers design, to heat-treated steel with a four-fold margin of safety, to aluminum castings; to drop forgings. With its deep upholstery and sinewy underslung springs, excessive weight is no longer essential to comfort and safety.

Its light weight and low price mean a double saving. A lower cost means economy once; lower up-keep cost means economy every day.

Built Up to a Standard, Not Down to a Price

The Master "Light Six" is built throughout to meet a standard, not to fit a price.

We use the best steel because we must hold up the strength while we hold down the weight. Valves of ordinary steel are cheaper, but our valves of Tungsten steel never warp nor waste power. Our molded oval fenders cost more than flat ones, but they pay for themselves in added beauty and utility. Every dollar in the price stands for a dollar of real value in the car.

The Price is Lower—Not the Quality

The selling price of the "Light Six" is lower than the Master "Six" because the cost is less. The horse power is less because the motor is lighter, the weight is less because the car is a bit smaller.

But it has the same Chalmers-Entz one-motion starter, the same non-stallable Master Motor. Its roomy body is the true streamline type with flush fitting doors and concealed hinges. Tires are carried at the rear, leaving the running board clear. Its tapering bonnet, underslung springs and oval fenders give it distinction in any company.

Master "Light Six" Touring Car - $1800
Master "Light Six" Coupélet - - $2050

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

A Ridiculous Proposal

THE country has been favored of late with disconcerting evidence of the ignorance of some members of Congress on the subject of our Navy. Lack of elementary knowledge in such high quarters on matters of grave national import is greatly to be regretted; and when to this is added the fact that there occasionally crops out evidence of an active spirit of hostility, the situation becomes deplorable. It was only recently that a certain Senator spoke contemptuously of service in our Navy as being a condition of "paid idleness"—willful misrepresentation which is as unjust to the honorable profession attacked as it is discreditable to its author.

And now comes Senator Weeks with his amazing proposal to place the fast scout cruisers of the Navy in service as carriers of mail and freight between New York, New Orleans, and the Pacific Coast ports of South America! There is no possible excuse for the introduction on the floor of the Senate of such utterly impracticable proposals as this; for it is a fact, which must be well known to every one of the people's representatives in Congress, that there is within a few minutes' reach of the Capitol at all times a body of expert advisers, not merely in the Navy, but in every other Government department, who are not only willing, but very eager to afford all possible technical information and enlightenment on subjects which the members may wish to bring up for discussion, either in the House or the Senate. If Senator Weeks had taken the trouble to submit his proposal to the technical advisers of the Secretary, he would have been instantly assured that to use naval vessels for the transport of mail and freight was *a proposition impossible from every point of view.*

In the first place, the transfer of vessels from naval to commercial service would violate one of the very first principles upon which an efficient navy is maintained, namely, that every ship shall be in such a condition of efficiency that, in the sudden crisis of war, it can instantly proceed to the appointed rendezvous in which the mobilized fleet is being assembled. Of all types of naval ships there is none whose service would be more quickly called for than that of the scouts, whose duties would require them to operate far in the van of the fleet, where they could obtain the earliest possible information as to the strength and destination of the enemy's forces

In these days of watchful preparedness when, as in the case of the German navy, from three fourths to four fifths of the principal units are maintained in full commission and active service, a decisive blow may be struck contemporaneously with the declaration of war, or even in anticipation of it. It has always been a characteristic of our foreign policy, and was never more so than to-day, that we have been reluctant to make any distribution of our military forces which might bear any hostile construction by the nation with whom we were conducting diplomatic exchanges. Our scout service, as we have shown in a recent article, is altogether too limited as it is; and were the only three distinctively scout vessels that we possess to be transferred, as Senator Weeks has suggested, to commercial work, it is perfectly conceivable that a sudden declaration of war might find the "Chester" at Valparaiso the "Salem" at Buenos Ayres, and the "Birmingham" in the Straits of Magellan.

If Senator Weeks had taken the trouble to inquire, he would have been told that one of the chief difficulties of the naval constructor is to find space for such equipment, stores, berthing accommodations, fuel, etc., as must be carried by a warship in the performance of her designated work. He would have learned that every pound of displacement and every cubic foot of space has been allotted, and that it would be impossible, without making serious changes that would destroy the efficiency of the ship, to find space for mail, freight, passengers or any other of the accommodations which are necessary for the service proposed. Furthermore, the motive power of a fast scout cruiser was not designed to give those economical results which are only to be achieved when a designer is left a free hand to design a ship for the particular commercial service for which it is being built.

Let us hope that this latest absurdity will be consigned to the early oblivion which it deserves. We had thought that puerile suggestions such as this belonged to an earlier day, when ignorance about naval matters, particularly on the technical side, was excusable on the ground of unfamiliarity. To-day, when there is so much reliable information published regarding our Navy, there is no possible excuse to be found for such amateur proposals as this.

The "America" Cup Contest

THE present year will go down in the annals of yacht racing as one of the most famous in the history of this noble sport. The coming again to our shores of the indomitable Lipton, this time with the fourth "Shamrock," has resulted in the construction of three defending yachts, one by the veteran Herreshoff, another by his most able American competitor, Gardner, and a third by one of the most promising of our younger designers, Owens.

Particular interest attaches to this year's series of contests, because of the fact that they will be held under a new rule of measurement, which discourages the building of the extreme and almost freakish type of yacht with which the public was made familiar in the last series of "America" cup contests. The old rule encouraged the construction of a yacht of extreme beam, draught, and over-all length, with a flat floor and full ends, and carrying an enormous spread of sail. The new rule governing this year's contests encourages a return to a more wholesome form, with a fuller and deeper body and sharper ends—a type which, after the races are over, is still serviceable for cruising because of its greater head room and its easier motion in a seaway. Furthermore, the more limited draught enables the yacht to enter harbors and cruise in waters which are inaccessible to the older type. When it is remembered that these manifest advantages are secured without any sacrifice of speed, the all-round advantages of the new rule over the old will be manifest.

In Nicholson, one of the younger designers, the challenger has at his disposal the genius of the most successful yacht designer, probably, in Great Britain. "Shamrock IV" will also have the advantage of being absolutely in charge of the most successful amateur yachtsman to be found in the British Isles.

Mental Acrobatics

THAT perfection in the solving of scientific problems is an art to be acquired by training, practice, and experience is so obvious a truth as to require no emphasis and to invite no contradiction.

Not so obvious is the fact that in the selection of problems for inquiry, in the mere asking of questions, much depends on the judgment and common sense of the inquirer. Indeed, it has been said that the great man in science is recognized not so much by the means he employs to attain his ends, as by the purposes toward which he bends his efforts.

The mind of man is so constituted that it must needs ask questions regarding things and events about him. And this is well; for to this inquisitive streak in his make-up we owe probably all the most fundamental discoveries of science; the other impelling agent, the desire to apply natural forces to useful ends, has probably played a less important rôle in the history of science, and has affected chiefly the development of detailed knowledge rather than the discovery of broad fundamental principles.

Now this impelling desire to "ask questions" has its drawbacks. The case is well illustrated in a simile drawn by the great German physicist, Ludwig Boltzmann. He likens the efforts of certain philosophers to those of a baby sucking at a feeding bottle: So long as there is milk in the bottle the baby sucks with gusto and effect; but presently the bottle is empty: still the baby goes on sucking. So, said Boltzmann, certain types of mind are set upon asking questions, and when they have exhausted all sensible questions in their repertoire, they turn to the consideration of vain and futile inquiries. The middle ages were particularly rich in mental gymnasts of this kind, but our day is not by any means free from acrobats who would essay a tight-rope dance across the chasm that separates us from the region—not of the unknown—but of the unknowable.

One of these vexed "problems," [illegible] to have an irresistible fascination [illegible] that of the "ultimate cause" of things.

Now such inquiries as this are a [illegible] for two reasons: first, because they [illegible] to any solution; and, secondly, because we can accomplish all our daily tasks and affairs perfectly well without waiting for such a solution. In other words, the inquiry is both fruitless in its results and useless in its applications.

If evidence is needed to substantiate these statements, let the reader reflect over this: If the search after causes were really so vital a function of scientific research, surely we should expect to find the word "cause" to recur somewhat frequently in works presenting the results of the most advanced phases of modern science. As a matter of fact, advanced sciences, like gravitational astronomy, even physics in general, never employ the term "cause." Indeed, the word could well be spared from the scientific vocabulary. "The word 'cause,'" says Bertram Russell in the *Proceedings of the Aristotelian Society*, "is so inextricably bound up with misleading associations as to make its complete extrusion from the philosophical vocabulary desirable. . . . The reason why physics has ceased to look for causes is that, in fact, there are no such things. The law of causality, I believe, like much that passes muster among philosophers, is a relic of a bygone age, surviving, like the monarchy, only because it is erroneously supposed to do no harm."

The fact is, the physicist has not only learnt to answer questions, but to ask them. He spends no futile efforts seeking to find the ultimate cause of an event; but instead, he studies the various *determining factors* which influence a given phenomenon. He measures each factor and the phenomenon studied, and seeks to find an equation or formula by which the one can be calculated when the others are given. In technical language, he seeks to discover the *functional relations* between the variables which appear in his problem. Once this is done, once his formula is found and proved correct by actual test, his task is finished, and any further inquiry after the "cause" of things seems a fit subject for an inmate of an institution very different in character from the physical laboratory.

Industrial Research and the Steel Rail

IN the course of his presidential address before the American Chemical Society, Arthur T. Little, speaking on the question of industrial research in America, showed how the steel industry in its many ramifications promotes an immense amount of research, which ranges from the most refined studies in metallography to experimentations upon the gigantic scale which was required for the development of the Gayley dry blast, the Whiting process for slag cement, or the South Chicago electric furnace. This last is the furnace which has formed the subject of considerable illustration and description in the SCIENTIFIC AMERICAN during the past two years. The president of the American Chemical Society is of the opinion that this furnace has probably operated upon a greater variety of products than any other electric furnace in the world; and he draws attention to the fact that up to the autumn of last year, after two and one half years of operation, no reports of breakages had been received from the 5,000 tons of standard rails made from steel produced in this furnace. That would be a significant statement under any conditions, and it is particularly so when it is borne in mind that, during the past thirty years, the average total weight on the drivers has increased over two hundred and fifty per cent. Thus, in 1885, the average total weight on drivers was 60,000 pounds; in 1907 it had risen to over 180,000 pounds, and in that same year it reached a maximum in a few locomotives of 316,000 pounds. Yet, in spite of this enormous increase in the concentrated load, the weight of rails during that same period had increased only from between sixty-five and seventy-five pounds to between eighty-five and one hundred pounds per yard. In the years preceding the introduction of the electric furnace and the manufacture of steel rails from its output, the breakages were so frequent that they constituted one of the most serious perils, if not the most serious, of railroad travel. Thus, in 1905 conditions were so bad that out of a lot of 10,000 tons, no less than twenty-two per cent were removed during their first year of service because of depression in the head of the rails.

As promoting the safety of railroad travel, the product of the electric furnace may well take rank with the Westinghouse brake, block signaling, automatic stops, and the steel car.

The Exploration of Albania is perhaps the most urgent problem in European geography. A society has been formed in Vienna to promote the investigation of this terra incognita, and one of its members, [illegible] of Graz, is about to undertake a preliminary [illegible] survey of the country, which [illegible] a year.

Electricity

Railroad Wires Underground.—As a result of the recent storms which crippled service between New York and Philadelphia by blowing down telegraph and telephone poles along the tracks, the Pennsylvania Railroad has decided to run its telegraph, telephone and signal wires in conduits underground.

High-Power Transmission.—At present there exists in Europe only one line carrying power at a tension superior to 100,000 volts; this is the 60 kilometer line at 110,000 volts equipped in Silesia by the "Lauchhammer Aktiengesellschaft." In the United States, on the contrary, distributions at high tensions have rapidly developed. There are more than fifteen transmitting current at a pressure higher than 100,000 volts, and over distances greater than 500 miles.

Electric Dock Equipment.—Quite an extensive electric outfit is used at the new docks on the Spree, at Berlin. The docks are well laid out for handling grain, as well as for receiving supplies of benzine in underground tanks, coal, brick and other freight, and the port is connected by tracks with the railroad. No less than 37 electric motors are used for the ten main cranes, while 28 motors serve for various conveyers for the grain docks. Numerous other cranes besides winches and elevators take upward of 20 motors. The whole is a model plant. Some 200 railroad cars are accommodated in the dock quarters, and most of the material is handled by electric devices so as to assure a rapid service.

Alternating Arc in Mercury Vapor.—It has commonly been supposed that it is impossible to maintain an alternating arc in mercury vapor, for low frequencies and moderate voltages. In a paper read at the Paris Academy of Sciences, it was shown that this can be done. The quartz tube is full of mercury and ends in two reservoirs in communication with the atmosphere. Placed in series is a self-induction enabling the short circuit current to be reduced to about 2½ amperes. The arc is started by breaking the column in the middle by causing the mercury to bubble. A true alternating arc is established, the two alternations being separated by a period of extinction of about one thousandth of a second.

German Army Searchlight.—The German army is making use of a type of field electric searchlight which can be raised to quite a distance above the ground by the use of a telescopic tubular pole, this being made in four sections. By means of a hand winch, the tube is extended to the desired height, so that the beam can be directed to advantage. The apparatus is mounted on a two-wheel truck which is coupled to a second truck with driver's seat so as to make a four-wheel wagon. On the ground, the searchlight truck is uncoupled, and set at the proper point. The mast portion is folded down flat against the framework when not in use. Current comes from a dynamo group on a special wagon.

Effect of the Eclipse on Radio-telegraphy.—The British Association for the Advancement of Science has issued a bulletin calling attention to the exceptional opportunities that will be afforded by the total eclipse of the sun on August 21st for studying the effect of light and darkness upon radiotelegraphy. The eclipse will be total along a strip extending from Greenland across Norway, Sweden, Russia and Persia to the mouths of the Indus. In Russia, the duration of totality will be a little more than two minutes. There are two main points calling for investigation during the eclipse. In the first place, the propagation of signal-bearing waves through air in the umbra and penumbra will probably obey laws different as regards absorption and refraction from those obeyed in illuminated air. In the second place, the strength, frequency and character of natural electric waves, and of atmospheric discharges, may vary. To investigate the propagation of signals across the umbra, it will be necessary to arrange for wireless telegraph stations on either side of the central line of the eclipse to transmit signals at intervals while the umbra passes between them. It is thus very desirable that the Scandinavian and Russian stations should transmit frequently throughout several minutes before, during, and after totality. But stations other than those favored by their proximity to the central line should endeavor to keep a complete record of the variations of signals during the eclipse. Stations in Europe west of the central line, and stations in the Mediterranean and in Asia Minor, may find noticeable changes in the strength of signals, particularly long distance signals, between the hours of 10 A. M. and 2 P. M., Greenwich time; and it is probable that the stations of India and East Africa, and ships in the Indian Ocean, may feel the effect of the penumbra in the afternoon. On the other hand, ships in the Atlantic, and fixed stations in Eastern Canada and the United States, will probably be affected by the penumbra in the early morning. At Montreal, the eclipse (partial) is at its greatest phase at 5:32 A. M. Standard Time. It is requested that those possessing the necessary facilities and willing to make observations during the eclipse, communicate with the Hon. Secretary, Dr. W. Eccles, University College, London, W. C., at the earliest possible date.

Science

An Exhibit of Rain-gages.—The British Rainfall Organization is arranging an exhibit in the science section of the forthcoming Anglo-American Exposition, one feature of which will be a collection of rain-gages, of the 1814 period and earlier, which will be placed side by side with the gages used at the present day.

Theodore Roosevelt and the American Museum of Natural History.—It is announced that Theodore Roosevelt will give to the American Museum of Natural History $2,000 when he returns to New York, and that he will assist it in raising $4,000 more to carry out explorations in South America which are to complete the work which he has begun.

Vaporized Tar as a Fuel.—The Indiana Steel Company, at Gary, is using coal tar as a fuel for some of its open-hearth furnaces. The tar is heated till quite fluid, and injected under the boilers with a blast of steam which, of course, atomizes the tar. It burns much like a jet of oil and steam, and is economical, since the Gary plant secures much tar from its by-product coke ovens.

Expedition Shipwrecked on Hudson Bay.—The Norwegian ethnologist Chr. Leden, who was commissioned by the Canadian government to make a study of the Eskimos in northern Canada, and was also making collections for Canadian, German and Norwegian museums, was recently shipwrecked on Hudson Bay, and lost his whole outfit. After suffering great privations, he reached Fort Churchill early in February.

Hardening Steel with Compressed Air.—The usual methods of hardening steel in oil, water and other special baths produce a great tension along the line of contact between the hardened and unhardened parts. A recent German improvement on this process is the use of a number of jets of compressed air playing on the hot steel. The zones of cooling are graduated beautifully by varying the number and spacing of the openings in the nozzle. A wide range of results is possible by adapting the shape of the nozzle to that of the work.

Pharaoh's Serpents.—A cone of mercuric sulphocyanate, when ignited, burns with the development of a tremendous amount of ash. The cone seems to swell and writhe away like a serpent, hence the name. Any boy can make the cones at little expense. To a solution of corrosive sublimate, add a few drops of ferric chloride. Dissolve potassium sulphocyanate in water, and slowly add this to the other solution, until, after stirring, a red color remains. Filter through a sheet of muslin and form the white curds into little balls or cones. Dry, and you need only touch a match to produce Pharaoh's serpents. Do not breathe the vapors.

Treating Yeast with Ozone.—A curious commercial application of ozone has just been developed in the brewing industry. Samples of brewers' yeast treated with ozone for five minutes show greater fermenting power than untreated yeast. During the first day or two, there is no gain, but after that ozonized yeast exhibits fermentative power markedly in excess of untreated yeast. The benefit comes from the inhibitive action of ozone on objectionable organisms, and also because the weaker yeast cells are eliminated and the stronger ones stimulated in fermentative power. In the brewing industry, the over-production of yeast cells is a great source of loss which will doubtless be lessened by ozonization.

The Lost Russian Arctic Expeditions.—The Russian government has at last decided to make a search for the missing expeditions of Sedov, Russanov, and Brussilov, and has bought two Norwegian vessels, the "Hertha" and the "Eclipse," for this purpose. The "Hertha," with a Russian crew, will go in quest of Capt. Sedov's expedition, which is supposed to have sailed last August from the north coast of Nova Zembla for Franz Josef Land, and has not since been heard from. The "Eclipse," with a Norwegian crew, and under the command of the veteran explorer Capt. Otto Sverdrup, will proceed to the Kara Sea in hope of locating the expeditions of Brussilov and Russanov, both of which have been missing since the autumn of 1912. The former set out to attempt the Northeast Passage, while the latter was last heard from when *en route* from Spitsbergen to Nova Zembla. The rescue ships are to sail from Christiania, June 24th.

Capt. Amundsen's North Polar Expedition, which, as originally planned, was to have sailed in the summer of 1913, and was postponed for a year in order to give the scientific staff more time for preliminary studies and training, has now again been postponed for a year; this time because it appears that the "Fram," the vessel in which the expedition is to sail, cannot reach San Francisco in time for an early start from that port. Last year, the little vessel sailed from Buenos Ayres to Colon, in the expectation of proceeding thence via the Panama Canal; on account of the delay in the opening of the latter, this route was finally abandoned, and the "Fram" started on the long journey around the continent in which she is now engaged. The further postponement of the expedition will be turned to advantage, especially in giving the explorers time to become expert in the use of aeroplanes, three of which are to be included in the equipment of the expedition.

Astronomy

The Duration of the Sun.—Adopting the well-known hypothesis of Helmholtz, which attributes the production of the heat emitted by the sun to its contraction, an idea can be formed of the sun's duration. If one gives to the sun a coefficient of expansion intermediate between that of mercury and that of gas, one arrives at the conclusion that it has taken one to three millions of years for the sun to contract to its present radius, in particular, it would have taken 10,000 years to contract from infinity to a radius twice its present radius. Finally, the sun will take 200 millions of years to contract from its present radius to half that radius, and even then its temperature at the surface will be 3,000 degrees.

Earth-Shine on the Moon.—When the sun has disappeared beneath the horizon and we no longer receive its rays direct, it also happens that its light continues to reach us, indirectly and feebly, reflected by the whole or part of the disk of the moon. Inversely, when a portion of the lunar disk is not illuminated directly by the sun, it happens that it is feebly illuminated by the earth-shine; that is to say, by the reflection that those portions of the terrestrial surface which are at that moment exposed to the sun. Mr. F. W. Very has endeavored to determine the brightness of the light received in this way by the moon and has measured the intensity of this light compared with the intensity of those parts of the lunar disk which are illuminated directly by the sun. The result is that the earth-shine on the moon is about 1,600 times feebler than the mean brightness of those portions illuminated by the sun a little before the first quarter.

Distance of the New Star in Gemini.—In the spring of 1912, considerable interest was excited by the sudden appearance of a brilliant star which became visible to the naked eye during some weeks in March and April. After May it was no longer visible except in powerful telescopes. Mr. Slocum has attempted to measure the parallax of this star, and hence to deduce its distance from us. Parallax is a measure of the change of perspective a moving object presents when regarded from two different positions Advantage is taken of the revolution of the earth in its orbit, and measurements are made at intervals of six months Mr. Slocum, with the great 40-inch refractor at the Yerkes Observatory, has taken fifteen photographs of the new star at three different periods of six months. Six comparison stars were selected as near the Nova as possible, and distributed approximately symmetrically round it. A discussion of the results shows that the Nova is about 296 light years away, so that the sudden blaze of 1912 corresponded to some catastrophe which occurred in the beginning of the seventeenth century

Double Stars in a Double Star System.—The two stars Mizar and Alcor form a double star system which can easily be perceived by the naked eye This was not the case formerly, as the Arabs used the resolution of the system into its two components as a test for good eyes It would seem, therefore, that this star has increased in brightness since the tenth century, a supposition which is supported by the fact that it is not mentioned by the ancients. The history of this star was familiar to astronomers when it was found, in 1907, that Alcor is itself a double star. It is now discovered, by Mr. Harlow Shapley, that Alcor varies in brightness, the variations having a feeble amplitude and a short period. The spectrum type of Alcor, which is a star A5, that is to say a white star with hydrogen predominating, and the doubling of the lines, announces a variation of the Algol type, i. e., by eclipse, rather than continuous variation It is supposed that there exists a couple of elliptic stars very close together and inclined on their orbit in such a way that the mutual eclipse is feeble or almost nothing, the variations of brightness resulting from their marked ellipticity.

The Stellar Magnitude of the Sun.—The classification of the stars into orders of magnitude depending on their apparent brightness was undertaken a little hastily, with the result that many stars have been found which are brighter than stars of the first magnitude. Aldebaran is a typical star of the first magnitude, but Sirius is much brighter. Consequently the system of classification has had to be extended. A star of the first magnitude is 2.5 times as bright as a star of the second magnitude; a star of the second magnitude is 2.5 times as bright as a star of the third magnitude and so on. Stars which are 2.5 times as bright as a star of the first magnitude are called stars of 0 magnitude, while stars 2.5 times brighter still are said to be of the —1 magnitude and so on. Prof. Ceraski has made measurements to determine the magnitude of the sun, reckoned in this way. By adopting different methods of measurements, he reaches very accordant results, and it appears that our sun is a star of the —26.5 order of magnitude, which means that it sends us as much light as 880 millions of stars of the first magnitude. At the distance of a little over four light years, i. e., about 29,000 times its present distance, it would be a star of the first magnitude, so that, considered as a star, it is nothing out of the ordinary.

Moving Pictures Without a Screen

A Remarkable Development in Kinematography

By the English Correspondent of the SCIENTIFIC AMERICAN

SOME five years ago a German experimenter, Herr Messter, as a result of some particular investigations, discovered that if moving pictures were projected by reflection in a certain manner, the stage could be set with scenery and properties, as for a regular play, with the result that the usual white screen could be eliminated, and that the photographic figures could be moved about within a certain area in such a manner as to convey the illusion that living performers were seen instead of photographic reproductions. He pursued his experiments, but was faced with the initial difficulty that only small figures could be projected, and this fact tended to destroy the illusion, since to maintain the latter, life-size portrayal of the performers was imperative. Another complexity which troubled him was the destruction of the coloring qualities owing to the high light necessary. This latter problem was overcome by utilising pierrots and clowns, in which only black and white dress and make-up were required. Such a limitation was a handicap, but, nevertheless, when such pictures were shown, considerable interest and wonder as to how the effects were obtained, were aroused. The fact that the figures were dwarfish, and yet apparently endowed with life, enhanced the mysterious effect. By patient experimenting the inventor at last overcame the latter deficiency, and having succeeded in getting his figures life size, public exhibitions of "Alabaster," as it was called, were given in Vienna with great success. The absence of the familiar white screen proved an irresistible attraction. At the Scala Theater in London the pictures, upon their presentation, proved an instantaneous success.

The explanation of the mystery is exceedingly simple. Kinoplastikon is no more nor less than a revival of the famous "Pepper's Ghost" idea, adapted to the kinematograph. Singing and talking effects are obtained by electrically synchronizing a talking machine with the acting.

The accompanying diagram explains exactly how the stage is set out. Some years ago a British kinematograph experimenter ascertained that, if moving pictures are thrown through a translucent screen to be projected finally upon a plate-glass mirror, the pictures stood out with greater definition, softness and plasticity. In this instance a screen formed of a kind of ground glass was placed in front of the projector lens. This is the basis of kinoplastikon.

The projector, instead of being set at right angles to the screen, as is usually the procedure, either in front or behind, is placed in the wings, as shown in the diagram. The picture thrown from the projector strikes the translucent screen *A* and passes through it. Instead of falling finally upon a white sheet it strikes a sheet of plate glass *B*, which is set at an angle of 45 degrees to the proscenium opening, and consequently to the audience seated in the theater. This plate-glass screen virtually occupies the whole of the stage, terminating at either end in side wings, while other wing settings may be introduced as desired In reality the plate-glass screen *B* acts merely as a reflecting medium to the translucent screen *A* At the rear of the stage, parallel with the proscenium opening, and consequently also at an angle of 45 degrees to the plate-glass screen *B*, is the rear back-cloth which is of sufficient dimensions to cover the whole of the proscenium opening, as in an ordinary stage setting. At a short distance from the back-cloth special side wings *E* are set, the opening left being coincident with the area occupied upon the plate-glass screen *B* by the image of the film. From *E* to the back-cloth *F* the stage slopes upward at 1 in 20, and constitutes a supplementary floor. When the figures are projected they appear to walk upon this latter at the point indicated by the dotted line *C*.

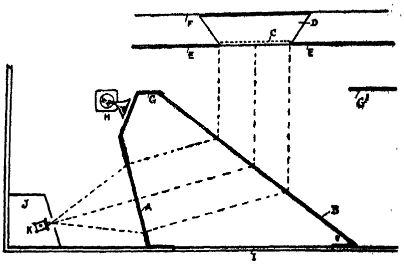
When the pictures are projected they pass from the projector *K* through the translucent screen *A*, and are seen upon plate-glass screen *B*. Here they are bent and apparently, from the audience's point of view, they appear at *C*, although as a matter of fact, it is merely the reflected images upon *B* which are seen. The latter being transparent the pictures appear to stand before the back-cloth *F*, and to all intents and purposes are alive and real players, because when walking off the stage they appear to pass behind the side wings *E* in the true legitimate manner.

The preparation of the pictures is carried out upon special lines. The studio has a back-cloth of black velvet forming a neutral background, while the figures for the most part are clothed in white, although this latter attribute is not essential in the latest development of the idea. But, as the background is a solid black, the images upon the film stand out against a transparent ground which in projection enables the figures to be *en silhouette* against the back-cloth of the stage setting. The density of the figures upon the film is sufficient to prevent the background from showing through the pictures seen by reflection, so that an apparent ghostly effect is neutralized. The figures in the film stand and move upon a vignetted base corresponding to the floor, and as this blends with the supplementary stage floor *D*, the figures, when projected, appear to stand upon the actual stage. The gramophone is set at *H*, which is as near to the actual apparent position of the players upon the stage as possible without suffering any depreciation in the volume of sound emitted. Were it set behind the side wings *E*, and level with the apparent position of the performers, the sounds would be muffled.

The talking machine and photographic records are not produced simultaneously, as with the Edison kinetophone and the Gaumont chronophone. The gramophone record is made first. Then the artists proceed to the theater, and act the play, repeating the words synchronously with the accompaniment of the previously prepared record. The gramophone is introduced to secure synchrony between lip movement, action, and sound. The operation is one of some delicacy, depending upon careful rehearsal and timing.

The talking machine system adopted is that known as the "vivaphone," which has proved remarkably successful. In the reproduction, striking coincidence between the action and lip movements of the artists and the talking machine is secured by means of a simple and effective electrical apparatus. In the projecting box is an illuminated indicator having an oscillating hand. The central position corresponds with dead synchrony between sound and movement. As the electrical apparatus of the gramophone is connected with the projector, the operator strives to keep this moving hand in the central position. On one side of the "synchrony" mark is a red light corresponding to "too slow," i. e., the pictures are in advance of the sound; while on the opposite side is a green light indicating action being behind the sound. If the former happens the operator decreases the handle turning speed, while in the latter instance the projector is accelerated. The indicator being in the projecting box, immediately before the operator, the latter has no need to watch the screen to see if he is keeping step. He merely follows the indicator. As in the majority of cases the projector is operated by electricity, the task of maintaining synchrony is exceedingly simple. This method of reproducing sound and movement simultaneously has proved the simplest, most effective, and most economical yet devised. After the gramophone record has been obtained, and should anything go wrong with the acting of the scene, or revisions appear essential, the wastage concerns the film only, whereas if the two different records are produced simultaneously, as in the Edison and Gaumont methods, a mishap, either in recording sound or movement, affects both issues, with the result that both have to be done again.

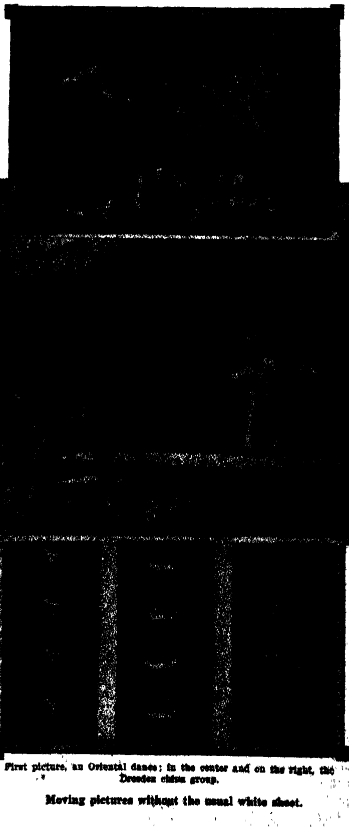
One very noticeable effect of this method of projection is the absence of flicker. The translucent screen appears to absorb all defects.



I, proscenium opening from the auditorium; *K*, the projecting machine in the fireproof box *J*, *A*, translucent screen set on left-hand side of stage, upon which picture is projected; *B*, plate-glass screen set at angle of 45 degrees to proscenium opening, bisecting clear part of stage, the inner end terminating in scenic wing piece *G*, *G*², opposite wing piece; *F*, back-cloth parallel with proscenium opening; *EE*, scenic wing pieces set to provide opening size of the image thrown upon plate-glass screen *B*, represented by the dotted lines from the bioscope From *E* to *F* the stage slopes upward at 1 in 20 to form a supplementary stage floor. When the pictures are projected *en silhouette*, as described, upon screen *B*, the feet of the figures appear to be on the stage floor at dotted line *C*.

Setting the stage for "kinoplastikon."

A representation of a Dresden china comedy.



First picture, an Oriental dance; in the center and on the right, the Dresden china group.

MODERN wars begin with all the surprise and violent shock of an explosion of dynamite—as witness the night attack by the Japanese destroyers at Port Arthur, which, even before the declaration of war, placed the Russian Pacific fleet out of commission and gave to Japan the command of the sea.

The striking of the first telling blow and the ability to follow it up are possible only when the belligerent, having set in motion a carefully prepared plan of mobilization, is able swiftly to concentrate the whole of his naval and military forces in the theater of war—as witness the fact that following immediately upon the Port Arthur attack, Japan transported to the mainland an army of 100,000 men in four days time.

Had Japan followed our own policy of unpreparedness, had she possessed no plan of mobilization, that is to say, had she left the work of organizing an auxiliary fleet to be done after war was actually upon her, as we did in the Spanish war, months of valuable time would have been lost, Russia would have been able to concentrate an overwhelming army in Korea and Manchuria, and the defeat of Japan would have been inevitable.

Mobilization is defined in the Dictionnaire Militaire as "the passage from a peace to a war footing, the period during which a 'navy' should be provided with everything which is necessary for it to go into a campaign and at once begin active operations."

The same authority goes on to say: "It is naturally important that this period should be as short as possible, for upon its efficient and complete achievement often depends the fate of the first encounters. Therefore, each nation has spared no pains to foresee in all their details the complex operations necessary to be carried out during this period of transition, so that when the time arrives, they may be executed without disorder, omissions or loss of time."

Have we any such elaborate system of mobilization?

The last attempted mobilization occurred in the North River, New York, in October, 1911, when there were assembled no less than 127 ships, including 31 battleships—an imposing array of naval *materiel*, which, if the individual ships had been fully manned and provisioned, and replete with full supplies of coal and ammunition, and if the fleet as a whole had included all the auxiliaries necessary to enable it to keep the sea, would have been a most formidable fighting force.

But what were the facts?

1. The ships in full commission were more or less depleted, both of officers and men, in order to furnish trained men to assist in handling the ships that were temporarily commissioned for the review.

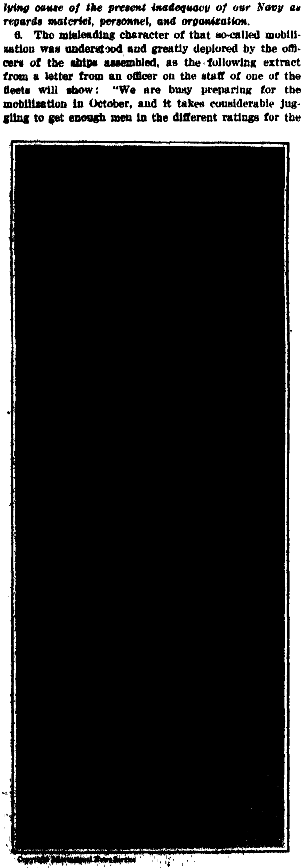
2. The ships sent to the review from the reserve were temporarily commissioned with skeleton crews, sufficient only for purposes of navigation.

3. The fleet included ships that were under repair, and new ships that were completing at a navy yard, which were towed by tugs to the North River and anchored there.

4. The greatly misleading impression of naval preparedness afforded by this so-called mobilization was not chargeable to an absolute lack of preparation; for the work of getting up this show of October was begun in the preceding July and August.

5. *The responsibility for this farce was not chargeable to the officers of the Navy. It was a political move, both in its conception and in its intended effect, and as such, it points with an unerring finger to the underlying cause of the present inadequacy of our Navy as regards materiel, personnel, and organization.*

6. The misleading character of that so-called mobilization was understood and greatly deplored by the officers of the ships assembled, as the following extract from a letter from an officer on the staff of one of the fleets will show: "We are busy preparing for the mobilization in October, and it takes considerable juggling to get enough men in the different ratings for the various ships. In fact, it looks as if we might have to leave one or two behind. We haven't yet managed to straighten matters out, though I dare say we will be able to pull through somehow. But the ships will have very slender crews—not enough to clean them; just enough to take them there and back."



Copyright International News Service

Rear-Admiral Badger, Commander-in-Chief of the Atlantic Fleet.

Such was our mobilization only so recently as 1911.

But how is it with the other naval powers? We have noted above the efficiency of the Japanese mobilization; now let us consider briefly two other countries which are fully alive to the necessity of a plan of mobilization that is capable of swift execution—England and Germany.

As regards the British fleet the procedure is as follows: From the Admiralty, London, a single telegram, consisting of the single word "Mobilize," is sent to each of four leading naval ports. This sets in motion the entire machinery of mobilization in all its details. These details are specified in complete mobilization plans, and in orders that define the duties of everyone concerned, whether with the military ships, auxiliaries, transports, colliers, supply ships, ammunition ships, etc. *So perfect is the mobilization system that all the fighting ships of the British Navy can be sent, in twenty-four hours time and without any previous notice, to the mobilization rendezvous, manned with regularly enlisted trained men, and fully provisioned and equipped*

There is no question as to the thoroughness of the German mobilization plans; for it is known that *the German torpedo flotilla can put to sea in two hours, fully prepared for war; the regularly commissioned battleships and cruisers in six hours; and the reserve ships not very long afterward.* No officer or enlisted man of the ships in commission is beyond the reach of recall within the time limit.

Mobilization, to become efficient, presupposes certain concomitant conditions, in all of which we are deficient, and in many of them unbelievably so. Chief among these are the following·

I. *War Plans.* Less than eighteen months ago, one of the most able and progressive officers of our Navy said: "When war becomes imminent, the question which must necessarily suggest itself is: 'What shall we have to do? What is the general plan of operations?' This must be the basis of mobilization and of all other preparations for war. It is a grave statement to make, but it is a fact that war in the immediate future would find us without a single adequate plan of campaign against any first-class power"

II. *Personnel.* A personnel sufficient in numbers to man the reserve ships and the auxiliaries, hastily recruited, but largely untrained, would render defeat probable. We have made no provision, adequate either in numbers or efficiency, for manning even the few fighting ships in reserve, not to mention the auxiliaries. Such increase as we might make would be mustered too late to be of use in the opening critical stages of the war against a well prepared enemy.

We deal with this subject in detail later in this article.

III. *Ammunition, Supplies, and Provisions* In a previous article we have shown how deplorably deficient we are in torpedoes and mines, having only about one round of torpedoes per tube and an even greater deficiency in mines and mining outfits. To realize the full efficiency of a mobilization there should be on hand a large reserve of supplies and provisions, coal, etc., and full provision for maintaining the supply either from Government or private sources, as the war proceeded.

Auxiliary Ships. Absolutely fundamental to any successful mobilization, is the listing of and provision for equipping the vast fleet of auxiliary ships, drawn from the merchant marine, which would be required to render the operations of the fighting fleet effective.

Foreign maritime nations list and inspect their merchant ships, assign their service in case of war, list the personnel and maintain the lists corrected to date, contract with the owners for chartering the ships, and in time of peace prepare the plans and material for their quick conversion for war purposes.

We are only now beginning to do this enormous work. It should be prosecuted with all dispatch, and Congress, so far as it lies in its power, should render every legislative aid and encouragement that it can.

Did we find ourselves suddenly at war with Japan, it would require two infantry divisions, totaling 40,000 men and 17,000 animals, to hold our possessions in the Pacific. This would call for over 100 vessels of nearly 350,000 gross tons for transport. Not one half of that number of vessels are available to-day in the Pacific that are suitable as transports. Our transport service would furnish only 50,000 tons. This would be the condition as regards the army; and the auxiliaries for army transport would have to be found after the naval auxiliaries, which in the nature of things would have the first call, had been taken up.

And this suggests the pressing need (for adequate naval warfare) of a large merchant marine.

But that is another story.

Naval Stations and Bases. The prompt equipment and supply of naval bases is a vital element in preparation for war, and a mobilization plan should provide for the rapid accumulation and transport of all necessary material. As matters now stand, we have not the stations and bases that our naval policy requires, nor the reserve supply of equipment, stores, and supplies to render them immediately useful in case of war.

Advance Base Outfits. In the second chapter of this series we drew attention to the fact that in Culebra (off the Porto Rico coast) and Guantanamo in the Atlantic, and in Hawaii, Unalaska, Samoa, and Guam, in the Pacific, we are in possession of a series of valuable strategic bases or outposts, the capture of which would be one of the very first objects of the enemy at the outbreak of hostilities. Our Naval Board has long recognized the importance of having a trained personnel in readiness to embark for these bases immediately upon a serious threat of war. We have the Marine Corps; but we should have on hand the advance base outfits; and the merchant vessels, suitable to serve as transports, should be listed and arrangements for their conversion into transports, etc., should be made beforehand. A few hours delay might mean the loss of an important base of operations.

The Need of a Trained Naval Reserve.

A successful plan of mobilization presupposes for its effective execution a numerous and well-trained naval reserve. *Instantly to expand the nucleus crews of the* ships in reserve to their full commissioned strength, to man the large fleet of auxiliaries, and to maintain on the receiving ships at the various yards a numerous reserve from which quickly to make good the wastage of war, would call for about double the number of men that are now by law allowed. The authorized enlisted strength of the Navy in time of peace is 51,500 men, Where, in the event of war, would the nation obtain the other 50,000? As matters now stand there would be two sources of supply: the Naval Militia and enlistment. The former represents a grand total of 7,817 officers and men, or about one sixth of the increase which would be instantly required. The other 43,000 would have to be secured by enlistment, a process which, taken in connection with the work of assembling and distributing the men, would consume many weeks of precious time and would involve delays in getting ships into commission that might well be fatal to success.

Our Naval Militia. As far back as the year 1888, the Government realized its need for an auxiliary force which might be drawn upon in the event of war, and in that year there was prepared the first naval militia bill, which failed to pass. The States, however, took independent action and organized Naval Militia forces, which, at the time of the Spanish-American war, represented a total of 4,445 officers and men, of whom, during the war, 4,000 officers and men were added to the Navy by enlistment. Most efficient work was done by the Naval Militia during that war; indeed, the "Yankee," "Dixie," "Prairie," and "Yosemite," if we except the commanding, executive, and navigating officers, were entirely officered and manned by the Militia. Since that time the Naval Militia has steadily increased in strength and efficiency, until it has reached a grand total of 7,817 officers and men, as mentioned above.

On February 16th, 1914, a Naval Militia act was passed which, according to Secretary Daniels, will do more, probably, for the encouragement of this arm of the service than any previous action of the Government. The leading provisions of the bill are that the President is authorized to call upon the Naval Militia in event of war; that the officers and men shall muster into service without further appointment or enlistment; that the Militia, when called into service, shall be governed by navy regulations; that the officers and men, when in service, shall receive the same pay as the same grade in the regular service; that the Secretary of the Navy is authorized to purchase or manufacture arms, accessories, equipment, etc., for the Naval Militia, the sum of $200,000 being appropriated for this purpose; that the Militia shall participate in cruises, maneuvers, etc., of the regular navy; that each State Naval Militia shall have at least five days for military or naval exercises each year; and that ammunition for target practice shall be furnished at the discretion of the Secretary of the Navy, the firing to be done under the direction of an officer detailed by the Secretary.

Much practical experience has been gained by the Naval Militia through the use of naval vessels loaned to the several States, and twenty-nine of these are now in use, the average cruise for which is thirty days each year. According to the Chief of the Bureau of Navigation, there is need for more ships. The vessels are old and many are withdrawn each year on account of age and for ever-recurring repairs. The Bureau believes that a type of ship of the size most suited for the Naval Militia requirements should be constructed to replace the vessels withdrawn.

This recommendation and all such for the benefit of this organization should receive the sympathetic consideration of Congress. It is eminently consistent with the spirit of the country that this body of patriotic, enthusiastic and efficient citizen-sailors should receive every assistance that can legitimately be rendered.

The Source of a Trained Naval Reserve.

While the efficiency of the Naval Militia is admitted, we have shown that its numbers are too small and its training is necessarily too limited, to enable it to provide that numerous and trained body of men which will be needed *instantly* at the *outbreak of war. In such a* crisis, the country would have to rely upon the ex-enlisted men of the Navy, who after four years of service, have passed out of the Navy into civil life. Now, while undoubtedly many ex-service men would instantly enlist at the beginning of war, much unavoidable and costly delay in manning the ships would be avoided if these men had been enrolled, organized, and assigned to their ships beforehand. These desirable conditions would be met if Congress authorized the formation of a naval reserve, the members of which would be required to put in three or four weeks of service at sea each year at full pay. As a further inducement, they might be paid, say, $5 per month during their term of enlistment.

Every year, about seven thousand thoroughly trained men, having completed their term of enlistment, are honorably discharged from the Navy and are merged and lost in the civil life from which they came. Among *these are skilled gun pointers* (worth, according to Capt. Plunkett, about $25,000 per man) quarter-masters, signal men, electricians, machinists, engineers, etc., all of them thoroughly familiar with the routine of ship life, men who, the moment they stepped aboard ship, would drop into the old routine with quick precision.

It is believed that the great majority of these men would welcome the opportunity to enlist in a Naval Reserve, and that the patriotism of the employers would find ways and means for excusing them for the annual period of drill. Such an arrangement, of course, would entail additional appropriations by Congress; but we can conceive of no direction in which the public moneys could be laid out to better advantage than this. There is every reason to believe that, by this measure, a thoroughly trained force, familiar with naval discipline and inured to the sea, would be quickly enrolled. If so, the Navy would have at all times within easy reach a sufficient force of trained men to complete the full complements of the fighting ships which are now held in reserve, in ordinary, or that are out of commission undergoing repairs.

Under the British system each man is assigned to a particular ship, and he knows to which navy yard to report upon notification. When the telegraphic term "Mobilise" has been sent out from the Admiralty and repeated throughout the kingdom, each postmaster, having the address of the various naval reserve men in his village, town, or district, instantly communicates with him. The man proceeds to the nearest railway station, where the ticket agent, upon identification, furnishes him his ticket and a prescribed amount of spending money to enable him to take the first train to the seacoast. The institution of some such method would enable our Navy Department, at the threat of war, quickly to gather all the needed reserves at the various receiving stations and distribute them aboard their several ships. Under such a system the whole of our fleet would be on its way to the [illegible] within a few days of the order to [illegible].

Within the last year, the Bureau of [illegible] established an Office of Naval [illegible] over 2,000 men have volunteered for [illegible] the opinion of the Bureau, Congress should [illegible] the formation of a National Reserve [illegible] would make the proposition attractive. If it should do so, the Bureau believes that there would be no difficulty in recruiting the full quota required in a very short time.

The Seamen of the Great Lakes. It has been suggested that a fruitful source of supply for the [illegible] of our ships might be found in the seamen of the Great Lakes. During several months of the winter the lake ports are closed and some 15,000 trained seamen are thrown out of work. It is believed that if Congress authorized a short term of enlistment, covering the winter months, a large proportion of these men, being absolutely without employment, would jump at the chance to enlist in the Navy. This body of men, being used to the seaman's life in deep water, would afford excellent material for the enlisted service. Sufficient men would be secured, probably, to man the reserve ships, which could proceed with the active fleet to the south coast of Cuba for the regular winter cruise, target practice, and drills.

Now it is believed that many of these men would remain in the Navy; and those that returned in the spring to the merchant service would probably wish to be enrolled in the Naval Reserve. In any case the country would be greatly benefited by thus interesting this body of practical seamen in the Navy, and enrolling, as it undoubtedly would, a large proportion of the 15,000 men in its trained Naval Reserve.

Drydocking in Canal Locks

By C. W. Fisher, Naval Constructor, United States Navy

ON December 12th, 1913, five submarines of the United States Navy with their mother ship or tender, the "Severn," arrived at Cristobal, Canal Zone. These boats are known as "C-1," "C-2," "C-3," "C-4," and "C-5." They were tied up alongside their mother ship, upon which the crews and officers live and mess, at one of the new concrete piers built by the Panama Railroad Company. This unique flotilla attracted great interest on account of its peculiar appearance, and its daily exercises in the harbor of Colon, where the small boats dived and maneuvered.

After four months of this duty it was found necessary to place the five submarines in drydock for the usual overhauling, testing and cleaning bottoms from the accumulation of barnacles and other marine growth. The small drydock at Mount Hope, near Cristobal, which was built many years ago by the French, and which is supposed to serve for all docking purposes until the big docks now under construction at Balboa are completed, about eighteen months hence, was unfortunately not available, on account of its being in constant use repairing the dredges at work on the big slide at Culebra. It was, therefore, necessary to devise some other scheme for docking these vessels, and it was decided to utilize one of the great locks at Gatun for this purpose.

Accordingly, on March 8th, 1914, the old "Severn," well known to many a midshipman, having served for years as a practice ship for the Naval Academy, now divested of her sails and machinery, was towed up to Gatun, accompanied by the five little submarines under their own power.

When the interesting fact became known that the very first navy vessel of any nation was about to pass through the locks of the Panama Canal and to enter Gatun Lake, large numbers of spectators gathered upon the walls of Gatun locks to witness this event, and on March 8th, 1914, the "Severn" was locked through and tied up to the approach wall of the Gatun locks in Gatun Lake, thus recording an important event in the history of the Panama Canal. On the following morning, March 9th, the submarines were locked through the east locks of Gatun and drydocked in the upper chamber.

These boats are cigar-shaped, and in order to land them successfully on the floor of the dock it was necessary to construct a cradle for each boat. These cradles were made in sections, of the exact shape of the underwater bodies of the submarines. The canal locks are not designed for use as drydocks, and, therefore, means had to be provided for holding the wooden blocking and cradles down on the bottom of the lock chamber to prevent their floating away when the chamber was filled with water. This was accomplished by bolting the sections to cross timbers placed in the culverts in the floor of the lock through which the water is admitted.

The walls of this lock chamber are [illegible] high, and vertical, and in order to accomplish the work of [illegible] the cradles it was necessary to [illegible] securely tied to the lock walls. [illegible]

[illegible] the boats [illegible] their own [illegible] chamber. [illegible] Here they [illegible] so that each might [illegible] the bows and [illegible] posts or battens to [illegible] holding the bows and [illegible] by members of the [illegible] bow and stern [illegible] under water, these [illegible] while performing [illegible]

[illegible] centered over their [illegible] the water slowly [illegible] settled in its par[illegible] was expressed by the [illegible] When the lock had been com[illegible] showed the landing to be [illegible] and the work of cleaning and overhauling proceeded.

In the midst of the work of overhauling the submarines an emergency arose requiring the docking of another vessel in this same lock. An explosion had occurred the night of the 11th instant in one of the oil tanks on the large ladder dredge "Corosal," which had been working in removing Cucuracha slide. This explosion did considerable damage to the bottom of the "Corosal," and drydocking in order to effect repairs was necessary. The "Corosal" drawing too much water to enter the drydock at Mount Hope, it was, therefore, imperative that she be docked in the other half of the chamber already occupied by the submarines. Similar blocking to that prepared for the submarines was at once installed for the "Corosal," the work being prosecuted day and night, and in four days the blocking was ready. She was docked on March 19th, 1914.

Owing to the fact that the same chamber as that occupied by the submarines was to be used, it was necessary to make some arrangement by which the submarines should not be disturbed when docking the "Corosal." The ordinary method in such cases is to float the ship already in dock and then land both ships at the same time. This, however, requires a large number of men to adjust the vessels accurately over their blockings or cradles; and it was here that the peculiar characteristics of the submarines were utilized to save time and money. Instead of floating these vessels, their tanks were filled, and they otherwise prepared themselves just as though they were to make a dive, so that when the water was let into the lock they remained securely upon their cradles, while the "Corosal" was being pulled into position over her own docking blocks.

Full crews and the commanding officers were on board each submarine, and as the water slowly rose in the lock they one by one disappeared through the conning tower hatch at the top of the boat, and took their stations below, until no one was left outside except the captain. When the water was close to the top of the boat, each captain in turn quickly entered the boat, pulled down the hatch, and as the water continued to rise, the boats were completely covered.

After the "Corosal" had been centered, the valves were again opened and the water removed from the chamber and the lock drained dry, and work at once begun upon repairing the damage caused by the explosion. This second docking in Gatun locks also brought out numerous spectators, because aside from the unexpected and unusual use of the lock chamber, the "Corosal" was one of the most important dredges working on the Cucuracha slide at Culebra.

While these two dockings were the result of necessity, as stated, and while the locks are not designed for such work, the results of these two experiences proved them fully capable of such use in addition to their designed functions as locks. And this means that in case of severe damage to any of the merchant marine or the United States Navy, these locks could be used as additional drydocks, if those to be constructed at Balboa were in use at the time.

So far as is known, this is the first time that submarine vessels have been submerged in such a way. The use of one of the lock chambers for drydocking in no way hampered the operation of the canal, since the west locks remained available for traffic in both directions.

The Problem of Three Bodies Solved

THE [illegible] of a mathematical problem is often deceiving. To one unfamiliar with the history of the case, it might be a matter of some surprise to be told that the greatest mathematicians had been baffled by that "simple" problem: To determine the path of three bodies acting upon each other according to the Newtonian law of gravitation, given their [illegible]

[illegible] two bodies is simple [illegible] be represented by a path having the form of one of the conic sections—an ellipse, parabola or hyperbola—with one of the two bodies situated at the focus, and the other traveling along the conic.

But as soon as a third body is added the problem is so increased in difficulty, that in the list of men who grappled with it unsuccessfully we find the names of practically all the greatest mathematicians since Newton, himself included. Euler, Lagrange, Laplace, Poisson, Gauss, Jacoby, Cauchy, Weierstrass, Poincaré, and Darwin all tested their powers on the task.

It has been reserved for a Finnish mathematician, Karl F. Sundmann, to furnish the long sought general solution (a number of particular solutions for special cases were known). The problem is a highly technical one, and it would be fruitless to attempt to explain in simple language the difficulties encountered and now successfully met in its solution. The artifice employed by Sundmann consists in the introduction of a new variable w in place of the time. The co-ordinates of the three bodies and the time can then be expressed as power series in w, which converges for all real values of the time.

From the point of view of mathematical theory the problem is, then, solved. But unfortunately, from a practical point of view, the solution is not satisfactory. It is not sufficiently transparent, does not readily answer the questions which the astronomer asks regarding the properties of the motion of the three bodies. The work of the mathematician in this field, though greatly advanced by Sundmann, is, therefore, not completed. No doubt others will follow along the lines which he has laid down, and, in fact, even now we can report a further advance, inasmuch as G. Armellini has extended the treatment to the case of n bodies.

Aviation in the British Army

AN important statement was made by Col. Seely recently with regard to the progress of aviation in the British army.

The present position of Great Britain may be summarised as follows:

1. The army has transferred its airships—there never were many—to the navy.
2. The army, in future, will concentrate on aeroplanes, which are being improved every day.

How many, then, of these all-necessary aeroplanes are possessed by the British army? The answer is 161, of which 100 were added during the last twelve months. There are to be eight squadrons, complete in men and machines, by the end of the coming financial year, and the total number required will be 250—50 for the Central Flying School, and 200 for the eight squadrons, twenty-five to each. But, as Col. Seely frankly admitted, if you want ten machines to be ready at a given moment, you must have twenty to draw on. Each aeroplane, in a word, must have a spare machine as its fellow, and the two can only count as one, so delicate are these machines, with so many things to go wrong and to give way.

Col. Seely also stated that he was providing for a large increase in the provision of spare parts, and for the creation of an Inspection Department. He spoke of his anxiety to do anything to lessen the risk of flying, and surprised the House of Commons by saying that there had only been six days in the year—barring Saturdays and Sundays—on which there had been no army flights; that there had not been a fatal accident to officer or man belonging to the military wing proper; and not a single breakage of any main part in the air.

The newest aeroplanes have an average speed of from sixty to sixty-six miles an hour.

The Current Supplement

IN this week's issue of the SCIENTIFIC AMERICAN SUPPLEMENT L. D. Allen writes on the manufacture and use of bearing metals.—E. E. Fournier d'Albe in an article "The Radiation Problem" gives a general survey of modern theories of radiation, with special reference to the "quantum" or "atomic" theory of light energy.—J. Whitman Bailey contributes an article entitled "A Comparison of Rivers."—The special organs by which animals are enabled to maintain their equilibrium and sense of the vertical direction form the subject of an article by W. Baunacke.—In an article on the wastefulness of coke ovens H. J. Freyn shows, among other things, how such ovens can advantageously be worked in conjunction with blast furnaces.—A profusely illustrated article is devoted to the remarkable work of Prof. Lehmann on liquid crystals, which, as our readers may recall, in many respects resemble living organisms.—The cost of electricity at the source is investigated by H. M. Hobart.—Prof. B. Hopkinson writes on the effects of the detonation of guncotton.—"Some Recent Advances in Piezochemistry" is the title of an article on chemical actions at high pressure by Prof. A. W. Browne.—The causes of Accidents with airships are discussed by E. Forlanini.

The Largest Fossil Bird Known

To the Editor of the SCIENTIFIC AMERICAN:

In the SCIENTIFIC AMERICAN of March 21st, 1914, you published an article of mine under the title "The Biggest Bird that Ever Lived." The title which I gave the article was "The Largest Fossil Bird Known." I call your attention to this difference in titles because I do not wish to assume the responsibility of calling the extinct bird that I described "The Biggest Bird that Ever Lived."

R. W SCHUFELDT.

Increasing Motor Output

To the Editor of the SCIENTIFIC AMERICAN:

In the SCIENTIFIC AMERICAN of March 14th, 1914, page 227, you published, under the heading "Electricity," a note calling attention to a method to increase the amount of power which a given electric motor can be called upon to furnish, and you attribute the method described to Messrs. Brown, Boveri & Co.

Permit us to state that the invention in question must be credited to Maurice Leblanc, and that it is covered in the United States in particular by two patents, 815,356 and 815,357, granted March 20th, 1906. These patents were assigned to Mr. Westinghouse.

Messrs. Brown, Boveri & Co. are our licensees.

SOCIÉTÉ ANONYME WESTINGHOUSE.

Scientific Photographs Wanted for the Royal Photographic Society Exhibition

To the Editor of the SCIENTIFIC AMERICAN:

The Royal Photographic Society of Great Britain is holding its fifty-ninth annual exhibition in August and September of this year. This is the most representative exhibition of photographic work in the world, and the Society is anxious to make it more international in character. It is very desirable that American scientific photography should be fully represented at the exhibition, and in order to enable this to be done with less work to the exhibitor, I have arranged to collect and forward American work intended for the scientific section.

This work should consist of prints showing the use of photography for scientific purposes, and its application to spectroscopy, astronomy, radiography, biology, etc. Photographs should reach me not later than Friday, July 10th. They should be mounted, but not framed.

I should be glad if any worker who is able to send photographs will communicate with me as soon as possible so that I might arrange for the receiving and entry of the exhibit.

C. E. KENNETH MEES

Research Laboratory, Kodak Park, Rochester, N Y.

Relative Cost of Tunnels and Bridges

To the Editor of the SCIENTIFIC AMERICAN:

The paragraph headed "Tunnels Versus Bridges" in the issue of March 28th, gives an erroneous impression while purporting to correct one. It considers the "capacity for a given cost" of a bridge and of a tunnel as proposed for the North River, and states what would doubtless be true, that "a bridge would accommodate five or six times as much traffic as could be sent through a tunnel," but it omits to state the equally important fact that the bridge is estimated to cost about five or six times as much as a *pair* of tunnels. Moreover, with a bridge this great carrying capacity is concentrated at one point, so that if it is to be used to its full capacity much of the traffic would have to make long journeys in order to reach the bridge, and again in order to reach its destination after crossing it. On the other hand, the several pairs of tunnels (one for traffic in each direction), which could be built for the cost of one bridge, would be distributed along the river so that the traffic could, in the average, pursue much more direct routes between the points of origin and destination.

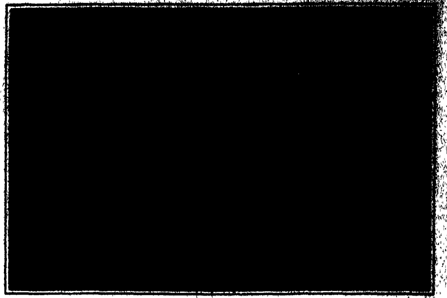
I call these facts to your attention, believing that you always desire to be fair to both sides of every question.

Media, Pa. JOHN LODGE.

[A North River bridge, costing $76,000,000, would have a capacity equal to that of nine pairs of tunnels costing, at $20,000,000 per pair, $180,000,000. Hence, the cost per single track would be two and one half times as much for eighteen single tunnels as it would be for a bridge of equal capacity.—EDITOR.]

It is predicted that western yellow pine will furnish an excellent source of turpentine as the southern pine becomes exhausted.

Forge furnace heating heavy work for the hammer.



Forge furnace burning a blast of coal dust. A great saving of fuel.

Powdered Coal for Fuel

Burning Coal Dust in Jets Like Oil

By Harry N. Holmes

THE use of powdered coal as a fuel has been developed to successful practice. It possesses all the advantages of burning an oil spray and the additional one of greater economy. Like oil, it is blown into the combustion chamber intimately mixed with a blast of air and is there completely burned with little or no smoke.

The comparison of values is interesting. Assuming that there are 19,000 British thermal units in a pound of oil and an average of 13,500 British thermal units in a pound of bituminous coal, and that gas producers will give 85 per cent efficiency, the following values are deduced: Oil at 4¾ cents per gallon, 28,600 British thermal units for 1 cent; producer gas from coal at $3.10 per ton, 69,673 British thermal units for 1 cent; powdered coal, slack, at $2.75, 98,181 British thermal units for 1 cent

To further this economy in operation a minimum of *attention is required, for the best equipment is almost* automatic in many details. Oil stoking requires little attention, and the two operations are similar in this as in other respects The absence of smoke is the natural result of the perfect combustion, as every minute particle of coal dust is completely burned in a proper installation. The intense heat obtainable by this coal dust jet will develop many special applications. One of the greatest advantages of this method of furnace firing is its adaptability to any grade of fuel, even coal that has no value on the grate bars. Anthracite, bituminous, lignite, coke breeze, all are grist to this sort of mill Experts consider that coal with 45 per cent ash has no steam raising value whatever when burned in the old way, but Barmhurst has obtained profitable results with coal of 52 per cent ash in a coal dust jet. This method of firing makes possible a tremendous development *of the low-grade coals of the West.*

There are four simple requirements which absolutely must be obeyed:

First—The coal must be dried so that it contains not over one per cent of moisture.

Second—The coal must be pulverized to a high degree of fineness

Third—It must be blown into a chamber hot enough to cause instant deflagration

Fourth—It must be supplied with air sufficient to yield the oxygen necessary to burn the carbon of the coal at once to carbon dioxide.

Drying the coal is essential for two reasons Coal containing much more than one per cent moisture is not easily ground to a fine powder. Furthermore, if this moisture were not removed in a drying oven it would be converted into superheated steam in the most expensive place for such energy consumption - the combustion chamber. This causes a very great loss in efficiency Fine grinding is essential in order to increase the free surface of every pound of coal Rapidity of combustion depends on this intimate contact of air and coal which is possible only with extremely minute particles. Very efficient grinding machines are on the market, producing any degree of fineness desired Some engineers consider that if 85 per cent of the dust passes a screen of 100 meshes to the linear inch, that is, each mesh is 1/100 of an inch square, the combustion results by this method will be satisfactory. Others make more rigid requirements, insisting that 85 per cent should pass a screen of 200 meshes to the inch.

Barmhurst states that 85 per cent of the dust will pass a 400-mesh screen and fully 70 per cent a 600-mesh screen, when ground by the best machines. Considering that each particle is a cube 1/600 inch on edge he estimates that a cubic inch of coal may break up into 216,000,000 such grains of dust. The surface exposed to air by a block of coal one inch on a side is only 6 square inches, hence such a cube burns slowly. The surface of this same cubic inch in the finest powder exposed to air in an intimate mixture is 3,600 square inches. Rapidity and completeness of combustion in the latter case is to be expected.

Too great a velocity of the fuel mixture does not permit the coal to develop its heat near the point of ignition where it is most needed, that is, at the entrance of the coal into the combustion chamber. To insure perfect combustion every pound of carbon needs 2 2/3 pounds of oxygen, which is found in 154 cubic feet of air. If less air is supplied much of the carbon burns to carbon monoxide, which escapes *from the stack or* burns in the stack without benefit. To utilize all the energy of the fuel the carbon must burn to carbon dioxide in the combustion chamber. Because of the extremely high temperatures obtained with coal dust, excess air is usually admitted to cool the gases somewhat. From 50 to 100 per cent excess is common in the best practice. When one pound of carbon burns with exactly 2 2/3 pounds of oxygen combustion should be complete, and, theoretically, a temperature of 4,859 deg. Fahr. be obtained, but with 4 pounds of oxygen, or 50 per cent excess, only 3,326 deg. Fahr. should be obtained, and with 100 per cent excess only 2,529 deg. Fahr. The color of the flame is a guide to the stoker in regulating the amount of air required for maximum efficiency. A short white flame is the hottest. The furnace must be so designed that the fuel shall be thoroughly consumed before its resulting gases are brought in contact with the work to be done, otherwise particles of unburned carbon will be chilled and appear as smoke.

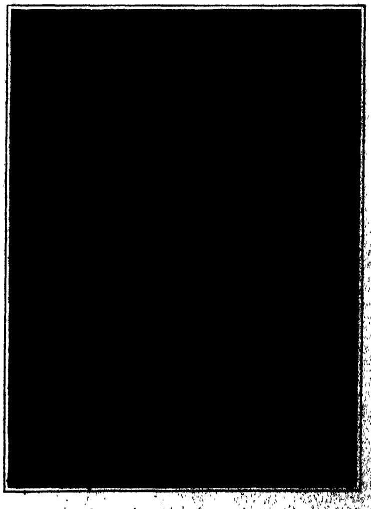
The process and machinery required are outlined by one of the best engineering companies as follows:

The coal is received in the pit of an elevator. This elevator carries it to the hopper of a pair of crushing rolls. Under this hopper may be an automatic weigh scale. From the hopper the fuel passes to an indirect fired coal drier. This drier must be of a size to deliver the required quantity continuously thoroughly dried. The drier is heated by a slow fire upon grates so arranged as to avoid igniting the drying coal. The cylinder of the drier is rotated by a small electric or steam motor. From the drier the coal drops into the pit of an elevator which carries it to a mill bin, set aloft. By spouts and gates the coal enters the pulverizer. By another elevator the fine dust is carried to the storage bins for powdered coal. These bins should hold enough to last during intervals that the pulveriser is not running. The coal is taken from the bottom of the bins by a worm feed screw, provided with a variable drive.

The feed screw delivers it into the burning pipe into which it falls. A fan forces a volume of air through the burning pipe, intimately mixing with the coal dust falling from the feed screw. The volume of air is easily controlled by either varying the fan speed, or by a blast gate.

There is no danger of a coal dust explosion such as occurs in mines, for the air and coal dust are not mixed until just as they enter the furnace at high velocity. A "puff" cannot take place against this inrushing column of air and coal. The air is introduced before the coal is turned on, and the coal is shut off before the air. If coal is introduced faster than it will burn, a great quantity of gas is distilled and gives the effect of an explosion, quite harmless, however. When the hot gases impinge directly on firebrick a cooling system of water-cooled pipe set in the walls may be necessary to save the brick.

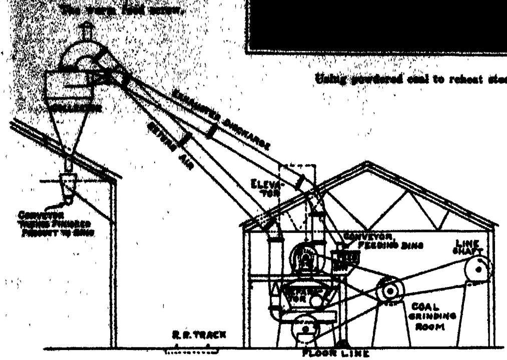
English practice in burning powdered coal differs somewhat from that used in America. The English favor a boiler, which uses rather coarse coal dust, containing up to 15 per cent moisture, for steam raising. Their practice is not to pulverize lump coal, but to utilize the screened dust from the mines, low in price, and reduce it to a powder not nearly so fine as that demanded by the American type. This practice



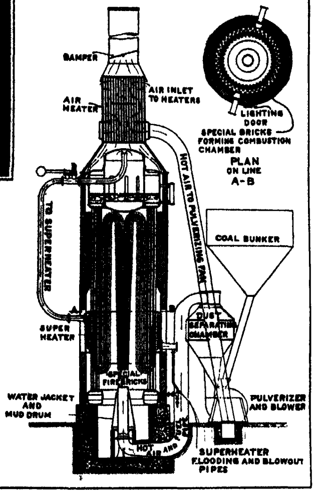
English type of boiler burning coarse coal dust.

[illegible]

Using powdered coal to reheat steel billets.



Typical mill for grinding coal and conveying it pneumatically to storage bins.



Cross section of the English type of boiler.

ing is done in a "beater" by fan blades of manganese steel at a speed of 1,500 revolutions per minute. Sufficient air is admitted in the beater for purposes of combustion. The fine particles are blown into the furnace through a nozzle. The coarser separate by gravity and are thrown back into the beater until reduced to the proper degree of fineness. There is no expense for drying unless the coal is above 15 per cent moisture.

The difficulties that delayed the development of a successful dust boiler are:

1. The difficulty of maintaining continuous and steady ignition, a difficulty met only by maintaining a uniform and very high temperature in the furnace.

2. The failure to find an economical material to stand the destructive temperature necessary as hitherto arranged for boiler firing.

3. The difficulty of producing a continuously homogeneous mixture with varying grades of coal, sometimes very wet and high in ash.

4. The difficulty of maintaining a homogeneous mixture of fuel dust and air during the full period required for complete combustion, the tendency of the larger solid particles being to concentrate in certain lines of direction, a difficulty met in part by extremely fine pulverization of the coal.

5. Difficulty of handling the molten ash which must usually form solid deposits of slag.

These troubles are overcome in the boiler here shown. It is of the vertical type and the tuyere is at the bottom, forcing the fuel dust and air with which it is mixed upward against the water tubes and brickwork at the top of the boiler. Thence the stream is turned down, enveloping the entering mixture with the highly heated products of combustion, and thus maintaining a regular ignition. The air mixed with the dust weighs about eleven and one half times as much as the coal and enters at considerable velocity. Since gravity and momentum act in the same direction in vertical firing there can be no separation of larger from smaller particles, a distinct advantage over horizontal firing. Of course the path of the particles is just great enough to permit the complete combustion of all the fuel. As in the American type it is necessary that the furnace be lined with brickwork of a highly resistant nature, not only to withstand the terrific temperatures, but to keep the fuel ignited by their incandescence.

Boiler tubes are built into the fire brick and, since they are vertical and a rapid stream of water is circulated, they collect very little scale. This is mostly formed in the bottom header where it can easily be blown off.

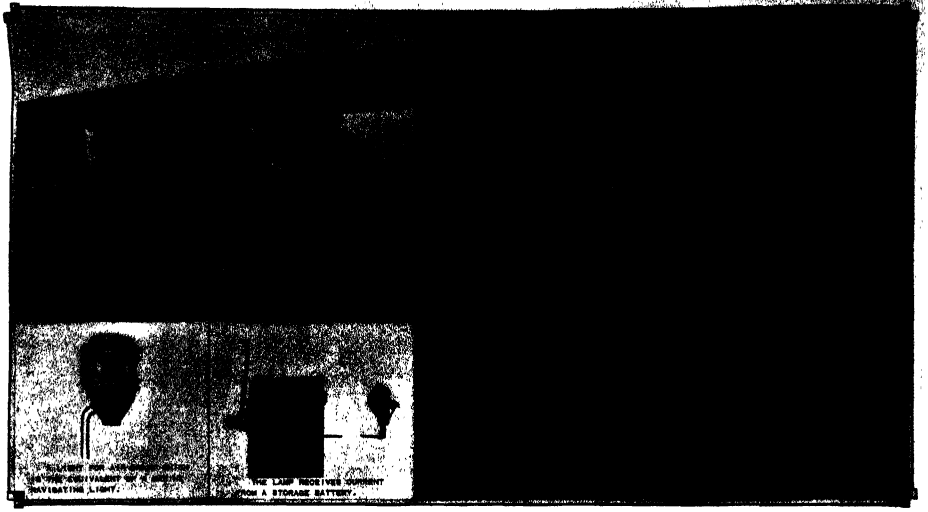
The Taxicab Service of New York City

By Harry Chapin Plummer

TRULY magnificent distances are those compassed by Father Knickerbocker in that vehicle which is so characteristic of the twentieth century—the taxicab. There are three thousand of those restless, snorting, erratic conveyances in service in the streets of Greater New York, and, barring a limited area in the Borough of Brooklyn and isolated sections of the Bronx and Queens, they are mostly all concentrated in the district

(Concluded on page 336.)

If a single taxicab could do all the work of New York city's three thousand, it would make nearly two round trips to the moon in one year.



Aeroplane lamps with lights of different colors, for showing their path and signaling their position when flying at night.

Aeroplane Lamps

A Light That Shows "Port" and "Starboard" and Also Throws White Beams Forward and to the Rear

By Dr. Alfred Gradenwitz

DIRIGIBLES are generally equipped with lamps fixed to the right and left, respectively, which, like those of ships on rivers or at sea, indicate the direction of traveling by red and green lights In a similar manner, it would be desirable to fit aeroplanes with two lamps giving out lights of different colors, thus enabling their position on the ground and their path through the air to be signaled and collision with other air craft to be prevented.

A manufacturer in Berlin has designed a special aeroplane lantern which would seem to comply with all requirements to be satisfied by such lamps While constituting no material extra load on the aeroplane and needing, under way, no attendance or supervision, it allows its position or direction of flight to be ascertained with all desirable accuracy.

This aeroplane lamp comprises a lantern casing inside of which there is arranged a 10 candle-power metal filament lamp whose light is so reinforced by an annular lens, that the luminous intensity actually given out amounts to about 40 Hefner candles The lamp is plainly visible, even in foggy weather, to a distance of about three miles Since the light is given out uniformly on all sides, the lamp is surrounded by a luminous ring. In order also to signal the direction of flight by means of this lamp, red and green glasses are so arranged in the interior of the annular lens that the forward portion of the luminous ring (about 10 degrees) appears white, whereas the adjoining part to the right (about 110 degrees) is colored green and the left-hand part of equal length, red The rearward portion between the red and the green parts (about 130 degrees) again gives out a white light This simple arrangement of the optical system enables any aeroplane equipped with the lamp to be sighted (and its direction of flight ascertained) at sufficient distance, the observer seeing more or less of the red or the green light beside the white.

The metal filament lamp is so designed that heavy shocks, as produced on landing, will exert no influence on it Moreover, its fitting is carried by a substantial spring, damping any jerks.

The incandescent lamp is fed from an Edison accumulator, arranged close to the driver's or observer's seat, which complies with all requirements of the case Replenishing with potash is only necessary every eight to twelve months, according to the actual strain on the accumulator. Refilling is effected exclusively with pure distilled water. Inclinations up to 45 degrees and heavy oscillations will not do any harm to the accumulator, nor will the electrolyte flow out. Recharging can be effected anywhere, the accumulator being readily removable.

It is recommended that the accumulator feeding the aeroplane lamp should feed at the same time a lighting plant for illuminating the instruments near the airman's seat, such as the speedometer, pressure gage, clock, gasoline gage, etc A 2 candle-power incandescent lamp fitted with a reflector and red glass pane is sufficient; in this connection red light being preferable in order that the airman may not be dazzled.

Each charge of the Edison accumulator suffices for feeding the aeroplane lamp and instrument lighting plant during seven lighting hours. The current supply to the aeroplane and instrument lighting lamps, respectively, can be switched in separately from the airman's seat. Whenever required, a keyboard may be inserted into the aeroplane lamp circuit, thus allowing signals to be given by its aid.

The whole lighting plant of an aeroplane, as above described, weighs about 10 kilogrammes (22 pounds).

Military Aviation in France

FROM a recent discussion of French military aviation in the *Engineer* and *Le Temps* we gather that there has been a serious crisis in the French aeroplane industry, accompanied by a disorganization of the military aviation department, where the apparent absence of method, and the poor results obtained after the expenditure of huge sums of money, have given rise to severe criticisms in the Senate. In the past two years 677 aeroplanes were purchased, and of these 175 were paid for by public subscription. Nevertheless, it is widely admitted that the aviation corps is wanting in homogeneity and efficiency. A mistake was made in trying to centralize everything relating to the technical development of the aeroplane and dirigible balloon at Chalais-Meudon. This department was perhaps a little too exacting at a time when the construction of aeroplanes was not so well understood as it is at present. Having fixed a standard of its own, and being unable to get aeroplane manufacturers to build machines to a new specification, Chalais-Meudon embarked upon the construction of a special type of military aeroplane. A large number of machines purchased from private builders were broken up within a month or two of delivery on the ground that they were lacking in structural strength. It is true that this action seemed to be justified by the alarming number of fatal accidents that had happened to military pilots. Chalais-Meudon has certainly not done better. The Minister of War has therefore given particular prominence to the reforms which it is proposed to carry out, such as the decentralization of the military aviation department and the offering of encouragement to private makers to co-operate with the military authorities in the building of suitable types of military machines. The present tendency is to develop an armored aeroplane which, in the words of the Minister, will be an "aerial destroyer." Improvements in aeroplanes and the organization of the military service on a sound basis require so much undivided effort that it has been decided to separate the aeroplane from the dirigible balloon, to which much more attention will be given in the future. Instead of sacrificing one to the other, both will be developed independently. The French government is having plans prepared for rigid dirigibles of 30,000 cubic meter capacity.

A Technical Museum for New York

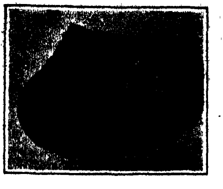
THE prospects that New York will have a museum comparable with the splendid Deutsches Museum of Munich are bright. It is announced that there will be established a group of twenty separate museums of as many industrial arts, to be known as the "Museums of Peaceful Arts." The proposed museums will cost $20,000,000, of which, it was said, the incorporators prospectively had already reason to count on about $1,500,000 as a nucleus. The objects of the corporation are given thus:

To establish and to maintain as a permanent and useful memorial of the century of peace and amity that has followed the signing of the Treaty of Ghent on Christmas Eve, 1814, in the city of New York, and for the people thereof, and for the benefit of the citizens of the State of New York and of the United States generally, buildings which shall be devoted to the housing and proper exposition of permanent exhibits in the following branches, among others, of the industrial and peaceful arts:

Electricity
Steam
Astronomy and Navigation
Safety Appliances
Aviation
Mechanical Arts
Agriculture
Mining
Labor
Efficiency
Historic Records
Health and Hygiene
Textiles
Ceramics and Clays
Architecture
Scenic Embellishment
Gardening
Roads and Road Building Materials
Commerce and Trade
Printing and Books.

A Sacred Clam Shell

THE clever priests of China often insert tiny images of Buddha within the shells of a living clam, which are left undisturbed for about a year. At the expiration of that time the images are covered with mother of pearl to such an extent that they appear to have grown in this natural manner. The Chinese people hold these shells in great reverence, believing that Buddha dwells within them. However, should a Christian chance to look upon one of the shells, it has no further value to them, as its charm is supposed to have left it.



Images of Buddha coated with pearl.

Afloat on the Dead Sea.

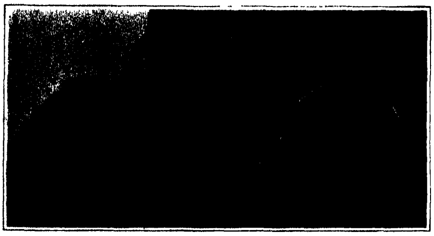
First Aeroplane in Jerusalem

DURING the last few months the aeroplane has made its appearance in many strange places, not the least among these being the ancient city of Jerusalem. It was during his flight from Constantinople to Cairo that M. Bonnier, the French airman, passed over the Holy City in his monoplane, descending upon the historic plain of Rephaim, a short distance south of Jerusalem. It was on this plain that King David met and defeated the Philistines. Never, in modern times, was the city so excited. It poured out *en masse* to see the airman and his machine—Christians, Jews, and Moslems. Our photograph depicts the airman about to leave for Cairo. The Holy City may be seen on the extreme left and the Mount of Olives on the right.

The first aeroplane in Jerusalem.

Revolving Cylinder Motor on a Motorcycle

THE revolving cylinder internal combustion motor, which failed so dismally on the single make of automobile on which it was used, but which since has "proved" itself in connection with the aeroplane, is due to have a tryout in motorcycle service. A machine mounting a three-cylinder motor of that type has been developed by a Connecticut inventor who now is completing arrangements to manufacture the machine in great numbers.



Motorcycle fitted with a revolving cylinder motor.

The motorcycle, which is pictured herewith, does not differ widely, exclusive of the motor, from accepted practice. The motor is mounted inside the rear wheel and concentric with it, so that the cylinders revolve in the same plane as the wheel. It is geared to the wheel by means of spur gearing, the ratio being four to one. In common with aeroplane motors of the same type, the carbureter supplies the mixture directly to the base chamber through a hollow shaft, whence it is admitted to the proper cylinder through the inlet valve, which is positioned in the piston and operated by means of a cam placed on the upper end of the connecting rod. The exhaust valves are in the heads of the respective cylinders, being operated by means of a stationary cam, tappets and tappet rods in the usual manner. Silence is approximated by causing the exhaust gases to pass through a series of comparatively small holes before emerging from the valve pocket. Ignition is effected by means of a set of batteries and a single coil operating in conjunction with a high tension distributer. While the maker claims that with a motor of this type it is perfectly possible to lubricate all parts by mixing the requisite amount of oil with the fuel, as is commonly done with two-cycle motors, for the present that system has not been adopted, and the oil is fed to the crankcase by means of a sight feed drip, and is circulated to the various parts by means of centrifugal force. A free engine clutch of the cone type serves to disconnect the engine from the wheel; it is operated by means of a lever on the handlebar.

The advantages claimed for the construction are manifold. Chief among them is light weight. The motor, which develops nine horse-power when run at normal speed, weighs about thirty-one pounds, and it is said that the motorcycle complete weighs fully a third less than any twin now on the market. Another big feature is the total absence of vibration, for the three radiating cylinders are perfectly balanced and there are no reciprocating parts with relation to the frame of the machine; hence the motor is perfectly balanced. In this connection, it is well to add that the intervals between the firing of the cylinders being equal, another reason for smooth operation and reduced vibration is evident By the same token, the torque is more nearly constant and the motor can be throttled down and run slower than even the best regulated twin. Other features claimed are certainty of cooling, for the cylinders constantly cut the air, whether the motorcycle is moving or not, and the elimination of drive chains with their accompanying noise and dirt The placing of the motor in such an out of the way position opens the way for the adoption of an open frame model for women riders.

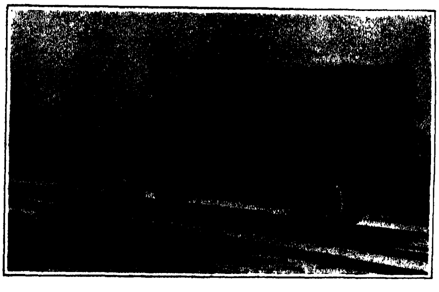
The apparent disadvantages of the type are inaccessibility of the vital parts, for the motor is closed in by the spokes, unequal distribution of weight, with the greatest amount on the rear wheel, tending to cause skidding; the delicate parts mounted where vibration is greatest and where there is no springing, which is not conducive to longevity Whether the advantages gained will be sufficient to outweigh the disadvantages, time will tell.

Floating on the Dead Sea

THE wonderful buoyancy of the Dead Sea, that strange inland sheet of water in Palestine, is proverbial It is some 47 miles long by 9 miles wide, and lies no less than 1,200 feet below the surface of the Mediterranean, the lowest-lying lake on the face of the globe Its waters are so bitter that fish cannot live in them We get an idea of its density when it is stated that in a ton of water from the Atlantic there is 31 pounds of salt against 187 pounds from a like quantity in the Dead Sea The result is that it is impossible for a human being to sink in these waters, and the accompanying photograph depicts a tourist reading his guide book while floating on the surface of the water

Mexican Armored Motor Car

THE accompanying photograph shows a standard American two-ton motor truck chassis which has been converted into a motor car by the Mexican Constitutionalists.

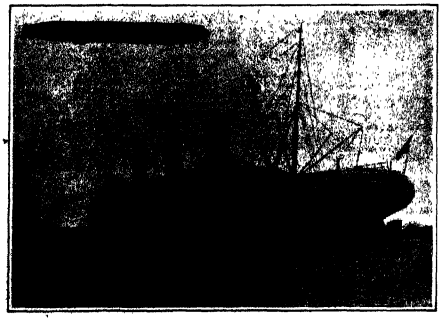


An armored motor car.

It was not known to what use the chassis was to be put when delivery was made to a southern dealer, but the result pictured is a striking reminder of the adaptability of the motor chassis, and shows the ingenuity displayed by the progressive Constitutionalists Interior space of the armored body is used for carrying ammunition, rifles, etc., while the deadly fire of machine guns can be directed through small portholes in the walls The car is fitted with armored wheels for operation upon the railroad, where a continuous stretch of track remains, or by quick adjustment the wheels can be changed to run over the roads directly into the *Zona Guerra.*

Two of the World's Seven Wonders

A SPIRITED voting contest has just been concluded in Germany to decide which are the seven wonders of the twentieth century. After the enormous volume of votes cast were counted, it was found that the majority had placed the wireless telegraphy at the head of the list and the Panama Canal second. The third of the seven wonders, it was decided, is the dirigible airship, next in order the flying machine, radium, the cinematograph, and the steamship "Imperator." An extraordinary photograph is reproduced herewith which shows two of the seven wonders of the modern world in close proximity By a lucky chance the photographer has caught the dirigible airship "Hansa" and the "Imperator" on the same plate The great airship, which measures more than 500 feet in length, was on one of her regular air cruises at the time she passed over the steamer.



A giant of the sea and a giant of the air.

Inventions New and Interesting

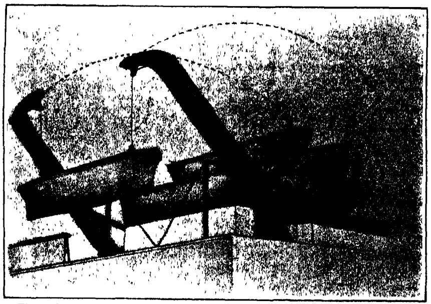
Lifeboat Arrangements on the "Britannic"

IT is certain that, up to within the last two or three years, the development of the lifeboat and its means for launching has lagged far behind the development of the ocean liner itself To-day, however, a great deal of thought is being directed, not merely to the construction of the lifeboats themselves, but to the provision of strong and effective means for getting them quickly and safely overboard, even when they are loaded to their full capacity We present two drawings which show the admirable way in which Harland & Wolff have worked out the problem on their new liner, the "Britannic," which will make her maiden trip to this port during the present year The lifeboats are nested, two deep, in groups of five, and each group is served by a pair of powerful electrically-operated davits. The old boat davits have always seemed to us to be rather primitive affairs, lacking in the necessary strength and rigidity, but no such charge can be laid against the installation on the "Britannic." The main members of the davits are of stiff lattice work construction, hinged at the decks and capable of swinging through a wide arc. Each pair can be swung over so far inboard that it can pick up a lifeboat from the center of the ship and swing it out so far outboard that the risk of its being crushed against the ship's side is practically eliminated. Access to the boats is gained by stairways which lead to platforms running between the several tiers of boats, from which the passengers can step conveniently into place. These stairways and platforms are not shown in our illustration; but they are sc arranged that the loading of the boats can be expeditiously done and without any confusion or crowding. The boat lowering gear is driven by electric motors of such power and so arranged that the lowering can be done very speedily, the boats being maintained on an even keel and released immediately on reaching the water.

The powerful davits of the new White Star liner "Britannic."



These davits can pick up a boat that is amidships and swing it entirely clear of a rolling ship.

A Smoke and Fume Monitor

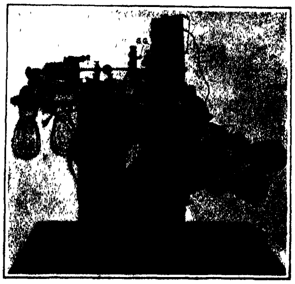
By W. W. Strong

MANY furnaces are not placed so that the fireman can see the top of the smokestack. Neither does the manager of the power plant often see the black fuel issuing from the top of the stack In other words, small account is given to this item of waste and the source of a fume and smoke nuisance in many cases

Naturally a fireman is not careful about the part of his work to which no one pays any attention The result is carelessness, and it is to this carelessness and lack of interest that much of the trouble of smoke inspectors is due. The purpose of the smoke monitor is to furnish an ever-present educational guide to the fireman, a conscience ever ready to prick at his contentment if he is not firing properly. The smoke monitor rings a bell and turns on a red light at the furnace door when the furnace is emitting smoke of a density forbidden by the city ordinance The smoke monitor works day and night, and a recording mechanism can be attached to it Besides the smoke monitor there should be a set of directions telling the fireman just what to do when the bell is *ringing*

The smoke monitor is a very compact piece of apparatus, and is entirely electrical in its action It uses from 60 to 100 watts of energy, and this is the only cost of maintenance, since there are no moving parts to the apparatus to get out of repair

In the illustration the monitor is shown with all the parts together, though it is probably more convenient to place the bell *B*, the red lights *RL*, and the relay *R* by themselves, while the transformer *T* is placed near the stack The transformer is a comparatively light one, giving about 20,000 volts potential (when on the 110 circuit) across the spark gaps *SG*. In parallel with this spark gap is a similar one placed in the smokestack. When there is little, if any, smoke in the stack the resistance is low and the discharge takes place in the stack When smoke of a given density (say one third black) appears in the stack, the resistance is so increased that the discharge takes place at *SG*, and this discharge is a series of oscillatory sparks The remainder of the apparatus consists of a coherer and relay and operates in the same way as in wireless telegraphy, turning on a bell and red lights whenever sparking takes place at *SG*. The apparatus can easily be carried about There are few adjustments necessary, these being the proper setting of the spark gap electrodes, the relay and the coherer. When there is no smoke issuing from the furnace fires, the instrument is perfectly quiescent As soon as smoke appears, the bell and red lights are turned on and remain going until the smoke ceases to be emitted The relay could be made to operate any other similar device such as draft mechanism, steam jets, etc



Instrument that sounds an alarm when a stack emits too much smoke.

Possibilities in Brush Invention

By H. M. Baxter

THE manufacture of brushes offers unlimited fields for the inventor, both in the production of a material to replace hog bristle, which is constantly growing more scarce and higher priced, and in the method of making the various sorts of paint, varnish, lather, hair, clothes and other brushes.

The following information regarding past efforts and present needs may be of assistance to any who wish to go into the matter.

Probably the most pressing need is for a rapid, inexpensive method of setting paint and varnish brushes. This setting or fastening must be absolutely impervious to the action of all liquids, including water, oils, alcohol, French spirits, turpentine, and the various distillations of coal oil, and should not necessitate the application of either heat or pressure. It should be adaptable to round, oval and flat brushes of all sizes and lengths.

The system of vulcanization is objectionable on account of its cost and because of the extreme heat required, which is naturally more or less injurious to the bristle. Furthermore, the vulcanizing process requires several days, delaying the manufacture.

Since the making of the first brush, a good setting has been striven for by all brush workmen and manufacturers. Most of these efforts have been to produce a cement that would dry, say, within twelve hours, or over night, and after drying, would resist the action of all liquids.

This result has been attained several times, but to make such a cement adaptable to present brush-making methods, it must remain in suspension, in an open, shallow pan, on the brush-maker's bench, throughout the working day, and so far there has been no single material which meets all these requirements.

Practically all bristle used in brush-making is produced in Russia, Germany, France, Siberia, and China. During the past five years there has been a steady increase in price with a corresponding scarcity in supply and depreciation in quality. Hair from horses' and cows' tails, various sorts of vegetable fibers from tropical trees, split quills from feathers, carefully tapered and prepared, and many other expedients, have been tried with little success, though many of them are used to adulterate the costly bristle.

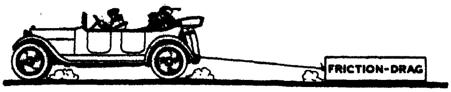
Some of the substitutes lack the requisite elasticity, others are too stiff and leave marks in the paint and varnish. And none of them possesses the marked "affinity" for oils and varnish that characterizes the hog bristle. Owing to its peculiar cellular formation and its natural oils, the "flag end" of bristle is a perfect paint and varnish smoother and distributer. This flag end consists of a tiny split or division into several parts of the outer end of the bristle, probably caused by the intense cold, in an endeavor to create a mat of warmth for the hog Therefore, a substitute for hog bristle must have some sort of satisfactory spreading power, to correspond with the "flag end." It must possess great strength and elasticity, so as to carry and spread a heavy load of oil and lead paint, yet must be fine enough to not leave marks in the paint or varnish. It must also have, to some degree, the power to pick up, carry along, and discharge gradually, a heavy load of paint, which is the most marked and valuable characteristic of hog bristle, owing to its cellular construction and oily nature.

A Simple and Convenient Fish Rod

AN ingenious combination of a spring balance and fishing rod can be made without disturbing the general appearance of the rod. All that is needed is to hollow the end so as to make a regular tube, or else fit on a short piece of tube. Part way up the tube is attached a spring, and the lower end of the spring carries a short hook for hanging the fish. The weight of the fish thus draws down the end of the spring in the same way as in the usual spring balance, and by cutting a small window in one side of the tube, a scale can be put on a piece of glass fitted in the window, corresponding to a pointer attached to the spring. The whole is simply a spring balance, built into the end of the fishing rod, and it is all inclosed and not in the way at ordinary times.

"Give me a quart of oil"

This careless request may bring costly penalties



The garage man comes out.

The motorist says, "Give me a quart of oil."

His "quart of oil" is poured into the crank-case or reservoir. The car goes on.

No doubt the motorist thinks he has amply protected the 1500-odd parts of his motor.

Far from it. *One of the surest ways to invite friction-drag and motor trouble is to say, "Give me a quart of oil."*

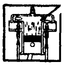
"Give me a quart of oil" *invites* Loss of Power

Escape of explosion past the piston rings, loss of compression and loss of power frequently result from oil of incorrect *body*. The power-loss is felt most on heavy roads and on the hills.

You can get full compression—complete power—only by using oil whose *body* suits *your* motor.

Correct *body* is seldom secured by saying, "Give me a quart of oil."

"Give me a quart of oil" *invites* Scored Cylinder Walls



Scoring frequently results from oil of low lubricating *quality*. Often, also, the oil's *body* is too light. Then the cylinder walls *have no protecting film*.

Scratching results.

Too often the blame can be traced straight to "Give me a quart of oil."

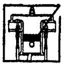
"Give me a quart of oil" *invites* Wear of Bearings

The problem of bearing-lubrication is far from simple. Bearings differ widely in type and size. The oiling systems which supply them also differ. Adjustments vary.

Both the *quality* and *body* of the oil must suit these conditions. For every oil that suits your motor bearings, you will find many which will cause undue friction.

An almost sure start toward bearing-trouble is, "Give me a quart of oil."

"Give me a quart of oil" *invites* Wear of Wrist Pins

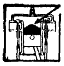


Wrist-pin lubrication is a difficult problem and little understood.

The location of the wrist-pins within the heated pistons and the slight angular motion of the bushings demand an oil which will spread readily, yet maintain the proper film between the pins and bushings.

Quick damage will come if the oil fails to meet these conditions. To encourage wrist-pin troubles prematurely, it is only necessary to say, "Give me a quart of oil."

"Give me a quart of oil" *invites* Carbon Deposit



Guesswork won't eliminate this trouble.

Both the *quality* and the *body* of the oil must be considered.

Suppose the *body* is too light for the piston clearance. The oil then works too freely into the combustion chambers. In burning, excess carbon accumulates unless the oil's ash is light and naturally expelled through the exhaust.

An easy road to carbon trouble is, "Give me a quart of oil."

"Give me a quart of oil" *invites* Noise

Noise is often a sign of worn parts—resulting from friction.

It may be a dull "thump" at every revolution of the main shaft. It may be "knocking" of worn wrist pins. It may be "hissing" within the cylinders. It may be "knocking" caused by excessive carbon deposit.

When a comparatively-new car pounds and racks its way along the roads it is seldom necessary to ask what brought on premature old age. Generally it is undue friction—resulting from incorrect lubricating oil. A way to invite premature noise is an off-hand request, "Give me a quart of oil."

"Give me a quart of oil" *increases* Maintenance Cost

If the oil's *quality* is low, a larger quantity is necessary to maintain a film.

If its *body* is incorrect, you have incomplete protection for the moving parts.

In either case excessive friction-drag results. Fewer miles are obtained from each gallon of gasoline. Your fuel and repair bills mount up.

This common waste is the frequent result of "Give me a quart of oil."

"Give me a quart of oil" *reduces* Second-Hand Value

What fixes the selling price of a used car? (1) The condition of the motor. (2) The condition of the chassis. (3) The condition of the body.

The motor is the vital part of the car. The motor condition, therefore, is most important.

At a recent sale in New York City, second-hand cars of uniformly prominent makes were auctioned off. The bodies were in good condition. The prices of the cars originally ranged from about $2000 to $5000. *The selling price in some cases was as low as $100.*

Why? Because the motors and other moving parts were badly worn

Was the wear due to long service? No. The age of most of these cars disproved that. *Premature* wear was evident.

It is safe to say the owners of these cars had used the common expression—"Give me a quart of oil." They paid a high price for their carelessness.

How to secure the correct oil for your car

Do not say, "Give me a quart of oil."

You want an oil whose *body* is correct and whose *quality* is best suited to the requirements of your motor.

Ask for that oil and get it.

Below we print, in part, our Chart of Automobile Recommendations.

This Chart is the result of the most far-reaching and thorough study of automobile lubrication that has ever been made.

It was prepared by a company whose authority on scientific lubrication, for every class of machinery, is recognized throughout the world—The Vacuum Oil Company.

It was prepared after a careful analysis of the motor of each make and model of American and foreign car

For a number of years this Chart has been the standard guide to correct automobile lubrication.

The superior efficiency of the oils specified has been thoroughly proven by practical tests.

Make a note of the grade of Gargoyle Mobiloil specified in this Chart for your car. Then make sure that you get it.

You will then give your motor oil of *body* and *quality* which will yield you the fullest power, the greatest freedom from friction, and the greatest pleasure in motoring.

If your car is not listed below, send for our *complete* Chart of Recommendations.

In buying Gargoyle Mobiloils, it is safest to purchase in original barrels, half barrels, and *sealed* five-gallon or one-gallon cans.

Look for the red Gargoyle on the container.

On request we will mail a pamphlet on the Lubrication of Automobile Engines. It describes in detail the common engine troubles—and gives their causes and remedies.

The various grades of Gargoyle Mobiloils, purified to remove free carbon, are.

Gargoyle Mobiloil "A"
Gargoyle Mobiloil "B"
Gargoyle Mobiloil "E"
Gargoyle Mobiloil "Arctic"

They can be secured from reliable garages, automobile supply houses, hardware stores, and others who supply lubricants

For information, kindly address any inquiry to our nearest office

A guide to correct Automobile lubrication

Explanation: In the schedule, the letter opposite the car indicates the grade of Gargoyle Mobiloil that should be used For example, "A" means "Gargoyle Mobiloil A." "Arc" means "Gargoyle Mobiloil Arctic." For all electric vehicles use Gargoyle Mobiloil "A." The recommendations cover both pleasure and commercial vehicles unless otherwise noted

The Price of $395 includes Top, Windshield, Lamps and Tools

A high-grade, well designed, carefully built, light-weight automobile, with four-cylinder motor, 96-inch wheelbase, roomy body, standard tread, standard features; produced by an experienced, soundly financed organization.

The Saxon is not a cyclecar, but a real automobile, so simple a boy can run it—the first car to offer all the essential features of standard motor car practice at a price under $500.

The first cost of a Saxon is less than a good horse and buggy; the upkeep cost far less. Saving in time considered it is cheaper than riding on street cars.

The Saxon is a car of the widest usefulness—a source of pleasure and health for those of moderate means, a great time-saver for salesmen, physicians, contractors and all others to whom time is money.

It is a car for the young man—or for the young couple. In a Saxon two people can enjoy all the pleasures of touring at a cost so low as to be negligible.

Here Are Some Saxon Features

4-Cylinder Motor, water cooled
Standard Tread
96-inch Wheelbase
Left Drive, Center Control, enter from either side

15 Horsepower
Sliding Gear Tranmission
More leg room than high priced cars
Streamline Body
Honeycomb Radiator

Dry Plate Clutch
Light Weight Oval Fenders
Wire Wheels
Good Looks
Low Upkeep

Saxons are selling fast everywhere. They are making good on all kinds of roads and hills, all over the country. See your dealer early for a demonstration. Send today for a detailed description of this sturdy car.

EDWIN C[illegible] CO [illegible] NEW YORK

The Taxicab Service of New York City

(Concluded from page 331.)

of Manhattan Borough whereof Times Square is the focal point. To utter the word "Taxi" in the vicinity of Times Square is to bring one of the gay-colored autocabs throbbing and pulsating before one at the curb.

The active season for taxicab service extends through about seventy-five per cent, or nine months of the year, but in that time the meters register the amazing total of 819,000 miles, almost four times the distance from the earth to the moon, which astronomers tell us is 221,000 miles in its nearest position. So Father Knickerbocker, seated in his fairly comfortable, if somewhat inelegant, taxicab, accomplishes yearly almost the equivalent of two round trips to the moon.

When the immensity of this mileage is taken into consideration, the physical capital which the industry in New York city alone represents and the earnings accomplished thereby seem relatively trifling. For $2,000 each would be a high valuation to place upon all of the taxicabs in service in the Greater City. Many vehicles are at the beck and call of patrons which have been condemned by the larger operating corporations and are valued in the open market at as low as $100; yet this average would mean a total valuation of no more than $6,000,000.

The most liberal estimate of the earnings of the taxicabs of New York would be $2,800 per year for the 75 per cent of the total number of machines operating throughout the year, and this would give an aggregate of gross earnings of $6,300,000.

"The Problem of Our Navy."

A SERIES of ten comprehensive articles on the present condition of our Navy, showing its unpreparedness, its present rating among the navies of the world, and what must be done to bring it up to its proper strength and position are being published consecutively in the SCIENTIFIC AMERICAN

Seven articles of this series have appeared in the issues of February 28th, March 7th, March 14th, March 21st, March 28th, April 4th, and April 11th, on the following subjects:

No. 1—"How the Navy is Daily Employed," by Hon. Franklin D. Roosevelt, Assistant Secretary of the Navy.

No. 2—"Sea Power and Our Foreign Policy."

No 3—"The Decline of the United States Navy to Third-Class Rank."

No 4—"The Price We Pay for Self-Sufficiency and Unpreparedness."

No. 5—"Battleship Strength Necessary to Guarantee Peace."

No 6—"The Shortage of Scouts, Torpedoes and Mines."

No. 7—"The Shortage of Officers and Men."

The eighth article appears in this issue.

No. 8—"The Need of a System of Rapid Mobilization"

Next week will be published:

No. 9—"The Need of a Council of National Defense."

The tenth and concluding article, written especially for this series, "The Navy is Not an Economic Waste," by Hon. Josephus Daniels, Secretary of the Navy.

Nelson's Tactics at Trafalgar are the subject of a recent report to the British Admiralty by a committee appointed to investigate the long-mooted question as to whether the plan of attack prepared by the great commander about a fortnight before the battle and communicated at that time to his captains was adhered to, or whether at the last moment a totally different plan was adopted, more or less by accident. The importance of this question consists in the fact that ultra-practical naval officers are prone to cite Nelson's alleged abandonment of his elaborate plan as an argument against naval tactics in general, claiming that in the heat of action tactics are forgotten. The report demonstrates beyond dispute that the plan drawn up on October 9th was carried out on October 21st in all essential respects.

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12977) E. M. B. asks: Are astronomers of the opinion that the telescope has attained its fullest scope? Do they think its power can be continually enlarged, so that after a while it may be possible to observe whether or not some nearby (relatively speaking) planet is inhabited? Or, as stated above, possibly the field of the telescope is limited, due perhaps to the molecular nature of glass (if glass can be said to be composed of molecules). A. The telescope is limited, but not because of the nature of glass. One limitation is in the Earth's atmosphere itself There are few nights when the highest powers can be used at all. The air is not sufficiently quiet and of uniform temperature. Other limitations are in the mechanical difficulties presented by large and heavy tubes, mounted to swing high in air, in the bending of large disks of glass suspended only by the edges, and the great increase in cost as the size is increased The disks of glass from which the 40-inch objective of the Yerkes telescope was made, weighed over a ton and cost $20,000. Many astronomers think that the limit in size of telescopes has already been reached.

(12978) F J. C. asks: Will you please tell me what is, or about, the voltage given off by an ordinary jump spark coil when wired to a set of new batteries, say testing 6 volts and 20 amperes? A. The voltage required to send a spark through air between sharp points is about as follows For a half inch, about 12,000 volts; for one inch, about 20,000 volts, for 1½ inches, about 28,000 volts.

(12979) L. P. asks: I ask your opinion or interpretation of the following, which is said to have been taken from an old work said to have been written in Egypt: "Make a magnet of the plusquam-perfection accompanied by the *prime material* of which all *metals grow*, and with this the magnet of the compass can be strengthened." What is plusquam-perfection (if anything) and what is the prime material of which all metals grow? A. The word "plusquam" is a Latin word, and means "more than." Applied to a magnet it should mean a supersaturated magnet, which will not retain all its magnetism. We doubt if the Egyptians knew anything about such magnets. There is no "prime material" from which all metals grow. *That is an old notion of the alchemists.* When the compass needle has been saturated, any further magnetizing is of no account. The needle will drop back to its ordinary strength as soon as the extra force is taken away from its vicinity.

(12980) S. A. W. asks: I want information concerning what I believe is called "Fermat's theorem." It is

$$x^{2+n} + y^{2+n} = z^{2+n}$$

when n is a positive integer About a year ago, I read in the SCIENTIFIC AMERICAN that a large prize had been offered for a solution I have a partial proof which I wish to submit A A prize of 100,000 marks (about $25,000) is offered by the *Academy of Sciences of Goettingen for the proof* of the greater Fermat theorem Fermat stated that the equation $x^n + y^n = z^n$ could not be satisfied by whole numbers when n is an odd prime number. This is the theorem to be proved to win the prize. We receive so many inquiries about this very attractive offer that we will state the conditions made by the Academy of Sciences for winning the prize It will not consider any manuscripts sent to it in competition for the prize, but will consider all memoirs which appear in the mathematical periodicals, or which are for sale in the book trade as monographs or as books The Academy requests the authors of such memoirs to send it five printed copies Memoirs in languages unknown to the judges must be accompanied by authentic translations. The award will not be made earlier than two years after the publication of the memoir for which it is awarded. The award cannot be contested During the two years, opportunity will be given to mathematicians to express an opinion upon the correctness of the solution selected, which will be made public. These are the principal regulations for the award. It is evident that only a complete mathematical solution may be offered. No partial solution will be considered. No one can send in a manuscript for the contest. A printed copy only will be received, published by some book house or in a mathematical periodical, which means that the solution must commend itself to some competent editor, or to a publisher as likely to be a profitable investment, in the first place. It must then meet the criticism of the mathematical world for two years after the Academy has approved of it. The Academy does not intend to be flooded with manuscripts which have not been endorsed by any one of prominence in the mathematical world. We trust that all our correspondents will note these points. They are abstracted from the offer of the prize in the *Bulletin* of the American Mathematical Society, October, 1908, pages 44–45. Also in the same periodical for November, 1907, page 92. We are indebted for this information to Dr. Joseph Bowden, Professor of Mathematics, Adelphi College, Brooklyn, N. Y.

Gasolene "VIM"
How Bowser Keeps It In
Saving Millions to Motorists Yearly

The annual loss to motorists through exposed gasolene is so enormous that it cannot be accurately reckoned in dollars and cents. It runs into millions. Gasolene stored above ground in ordinary containers soon loses its VIM. That Vim is what makes the car go. Bowser keeps the Vim in. The saving, economy and safety are great. Read on, and learn how and why!

Bowser efficiency and economy in oil storage started with the self-measuring oil pump invented by S. F. Bowser, the active head of this Company. The Bowser idea has grown until today there are 500 different

BOWSER ESTABLISHED 1885 Oil Storage Systems

In The Garage

Underground Bowser tanks keep all the original VIM of the gasolene in. It *can't* escape by evaporation or constant changes in above-ground temperature. No dirt can get in. No gasolene stolen, spilled or wasted. *No lost power.* No gas trouble to blame on the car. Pipe and pump it any distance into garage. Absolute safety. Utmost efficiency.

Also Bowser underground systems and tanks on wheels for the commercial garage.

In Stores

Keep kerosene, paint, lubricating oils, etc.—safe from changeable temperature, fire, theft, and away from other merchandise. No loss. No hazard. No spoiled merchandise. No groping for oil in the dark

In Factories

From simple departmental oil storage units to large filtering and circulating systems. Compel accuracy and efficiency. Check and use every drop of oil. Bowser Systems enable you to use the same oil over and over again.

Ask Bowser

Put your oil storage problems up to Bowser—whether of garage, store or factory Bowser has been solving just such problems for over twenty-nine years. Ask questions Costs nothing to find out. No obligation. Learn the added efficiency, the economy, the safety, the *comfort* and utility of Bowser service. Send the coupon today—NOW.

Unseen Forces Behind Your Telephone

THE telephone instrument is a common sight, but it affords no idea of the magnitude of the mechanical equipment by which it is made effective.

To give you some conception of the great number of persons and the enormous quantity of materials required to maintain an always-efficient service, various comparisons are here presented.

The cost of these materials unassembled is only 45% of the cost of constructing the telephone plant.

Poles
enough to build a stockade around California—12,400,000 of them, worth in the lumber yard about $40,000,000.

Telephones
enough to string around Lake Erie—8,000,000 of them. 5,000,000 Bell owned, which, with equipment, cost at the factory $45,000,000.

Wire
to coil around the earth 621 times — 15,460,000 miles of it, worth about $100,000,000, including 260,000 tons of copper, worth $88,000,000.

Switchboards
in a line would extend thirty-six miles — 55,000 of them, which cost, unassembled, $90,000,000.

Lead and Tin
to load 6,600 coal cars — being 659,960,000 pounds, worth more than $37,000,000.

Buildings
sufficient to house a city of 150,000—more than a thousand buildings, which, unfurnished, and without land, cost $44,000,000.

Conduits
to go five times through the earth from pole to pole—225,778,000 feet, worth in the warehouse $9,000,000.

People
equal in numbers to the entire population of Wyoming—150,000 Bell System employees, not including those of connecting companies.

The poles are set all over this country, and strung with wires and cables; the conduits are buried under the great cities; the telephones are installed in separate homes and offices; the switchboards housed, connected and supplemented with other machinery, and the whole Bell System kept in running order so that each subscriber may talk at any time, anywhere.

NEW BOOKS, ETC.

The Cause of the Social Evil and the Remedy. By Albert W. Elliott, President and General Manager the Southern Rescue Mission. Atlanta, Ga.: Webb & Vary Company, 1914. 16mo.; 144 pp.

In so far as this book deals with actual conditions and personal observations it is well worth a careful reading. The author's experiences have led him from the belief that the remedy lies in legal suppression, or even in reformation, through a dawning conviction that social vice is more a matter of the well-to-do and "respectable" classes than a mere problem of the underworld; until at length he sees that the fundamental causes must be sought elsewhere than in economic conditions. The weakest portion of the work is that dealing with "the remedy." The author himself seems to realize his helplessness here, for he is converted to the theory of toleration, though not of license, and he leaves the problem substantially as he finds it

Electric Light and Motor Wiring. By George J. Kirchgasser. Milwaukee, Wis.: Electroforce Publishing Company, 1914. Price, $1.

This is a book small enough to fit into the vest pocket, yet containing a great deal of up-to-date information on ordinary wiring. The National Electric Code requirements are cited, different systems are described in detail, and the illustrations and diagrams average at least one to a page

The Origin of Earthquakes. By Charles Davison, Sc.D., F.G.S. Cambridge: The University Press. New York: G. P. Putnam's Sons.

In a small compass, the author has explained earthquake phenomena, earthquakes and the growth of faults, discussed some simple earthquakes and their origin, as well as twin earthquakes and their origin, complex earthquakes and their origin, illuminated the subject of fore and after shocks, discussed sympathetic earthquakes and their origin, as well as earthquake sounds and their origin, and thus given the reader interested in popular science a good *résumé* of modern seismology.

Links with the Past in the Plant World. By A. C. Seward, M.A., F.R.S., Professor of Botany in the University of Cambridge. Cambridge: The University Press. New York: G. P. Putnam's Sons.

In this book, the reader who seeks only the facts of an important science presented in a popular way will find a very readable account of the botany of the present compared with the botany of the past. The subject is one which is fascinating, one which has a wide popular appeal. It lends itself admirably to presentation in simple form Prof Seward has made the most of his opportunities

The Migration of Birds. By T. A. Coward. Cambridge· The University Press. New York: G. P. Putnam's Sons.

In this popular book will be found the more important theories on the migration of birds and a discussion of speculations and evidence. The subject is a controversial one Almost every student of bird flight has his own views. While, therefore, it is very difficult to write impartially, we believe that Mr. Coward has acquitted himself very creditably

An Introduction to Experimental Psychology. By Charles S. Myers, M.D., Sc.D., Lecturer in Experimental Psychology at the University of Cambridge. Cambridge: The University Press. New York: G. P. Putnam's Sons.

The author has selected various topics which may be considered fairly typical themes of research in experimental psychology, such, for example, as color-vision, touch, temperature, the Mueller-Lyer illusion, experimental aesthetics, memory, mental tests and their uses; and these he has presented in such a form as will give the educated reader a general notion of the scope of the science and of the experimental methods it employs

The Natural History of Clay. By Alfred D. Searle. Cambridge: The University Press. New York: G. P. Putnam's Sons.

Mr. Searle has stated, in a simple form, an outline of present knowledge of the subject of clay, and has indicated the problems which still lie before the clay worker First he discusses the chemical and physical properties of clay and then passes on to clay and associate rocks, the origin of clays, the modes of accumulation of clays, some clays of commercial importance, and clay substances; theoretical and actual. A good bibliography and index concludes the book.

The Wanderings of Peoples. By A. C. Haddon, Sc.D., F.R.S., Cambridge: The University Press. New York: G. P. Putnam's Sons.

This book is a brief survey, written in popular language, of the trend of human migrations so far as present knowledge permits. The author has covered various periods of human history, even going as far back as the earliest diffusions that can be predicated.

The Work of Rain and Rivers. By T. G. Bonney, F.R.S. Cambridge: The University Press. New York: G. P. Putnam's Sons.

In this book, persons of ordinary education will find all that they need to know of this interesting subject. The use of technical terms has been avoided, as well as the discussion of controversial points.

"STAR" [illegible] LATHES
[illegible]
SENECA FALLS MFG. CO.
695 Water Street
Seneca Falls, N. Y., U.S.A.

For General Repair Work
GOOD LATHES—PRICES RIGHT
Made of high-grade materials by expert workmen. Drop a card for our latest catalog.
THE SEBASTIAN LATHE CO., 120 Culvert St., Cincinnati, O.

Friction Disk Drill
FOR LIGHT WORK
Has These Great Advantages:
The speed can be instantly changed from 0 to 1600 without stopping or shifting belts. Power applied can be graduated to drive, with equal safety, the smallest or largest drills within its range—a wonderful economy in time and great saving in drill breakage.

A Million Dollars a Year

THERE is a man in northern Michigan who makes personal sales of one million dollars a year, all to people of small incomes.

In New England there is a small town merchant who bought a bankrupt store for $200, and in a few years turned it into a business with $100,000 annual sales.

In Illinois there is a man who started at the bottom of a big corporation less than twenty years ago, and now, at the age of 35, has reached the top.

Would you like to know how these men succeeded? Would you like to know their inside methods, their vital, business-building plans?

We have just printed a book, which we will send you free on request, that will show you how you can learn the methods of these men, and many others like them, in all lines of business. This book, called "The Open Door," points the way to bigger business, more profits and a larger income. Write for it today. Simply say on a postal: "*Send me your Open Door book.*" Address

$3.00 A Year

Fuel and Repairs

You can lower these expenses

In three years' time supplies and repairs occasionally cost as much as the original price of a car.

Careless lubrication is responsible for most of this expense.

A canvass among New York repair shops showed that about one-half of the automobile engine troubles are caused by incorrect lubrication.

There are two things that must always be considered in an oil. One is its quality. The other is its fitness for your motor.

Low *quality* oil in time may bring practically every trouble a motor can face.

Oil of a *body* which is incorrect for *your* motor brings many penalties--heating and seizing of bearings, worn wrist pins, poor compression, breaking of parts, excess carbon deposit, smoking or overheating of engine and many other troubles.

Aside from repair troubles you must face a plain fact.

The more power you waste the more fuel you must consume

You cannot get perfect lubrication unless the *quality* is right, and the *body* of your oil suits—

(1) Your type of lubrication system.
(2) Your piston clearance.
(3) Your bearing design and adjustment.
(4) Your bore and stroke
(5) Your engine speed
(6) The size and location of valves.
(7) Your cooling system.

Gargoyle Mobiloils are sold *by a Chart* which specifies the correct grade for each car.

They are backed by almost 50 years' experience which has won for us the world-leadership in scientific lubrication

If you do not at present use the grade of Gargoyle Mobiloils specified for your car, you may feel almost certain that your bills for fuel and repairs are higher than they should be

Consult the partial Chart printed at the right. Make a note of the grade specified for your car. Then make certain that you get it. If your car is not mentioned send for our complete Chart of Recommendations.

It is safest to buy in original barrels, half-barrels and sealed five and one-gallon cans See that the red Gargoyle our mark of manufacture, is on the container

On request we will mail a pamphlet on the Lubrication of Automobile Engines It describes in detail the common engine troubles and gives their causes and remedies.

Correct Lubrication

Explanation: In the schedule, the letter opposite the car indicates the grade of Gargoyle Mobiloil that should be used For example "A" means "Gargoyle Mobiloil A." "Arc." means "Gargoyle Mobiloil Arctic." For all electric vehicles use Gargoyle Mobiloil "A." The recommendations cover both pleasure and commercial vehicles unless otherwise noted.

The Modern Gasoline Automobile

Its Construction, Operation, Maintenance and Repair

By VICTOR W. PAGÉ, M.E.

Covers Every Phase of Modern Automobile Practice. Latest and Best Treatise

Over 800 (5½ x 8) Pages 11 LARGE FOLDING PLATES 575 Illustrations

Price $2.50

The latest and most complete treatise on the Gasoline Automobile ever issued. Written in simple language by a recognized authority, familiar with every branch of the automobile industry. Free from technical terms Everything is explained so simply that anyone of average intelligence may gain a comprehensive knowledge of the gasoline automobile The information is up to date and includes in addition to an exposition of principles of construction and description of all types of automobiles and their components, valuable money-saving hints on the care and operation of motor cars propelled by internal combustion engines

TO THE 1914 REVISED EDITION

Entirely new material has been added on tractors in three and four wheel forms, cyclecars and agricultural tractors or automobile plows; combination gasoline-electric drive, front-wheel and four-wheel drive and steer systems and other important developments in power propelled vehicles. The discussion of power transmission methods has been augmented by consideration of the skew bevel gear and two-speed direct drive rear axle, as well as several new forms of worm gear drive. The subject of electrical motor starting systems has been considered at length and all leading systems and their components described. A discussion on ball and roller bearings, their maintenance and installation, has also been included, and a number of other features of timely interest such as latest types of gasoline and kerosene carburetors, cyclecar power plants, the Fischer slide valve motor, detachable wire wheels, etc., have been added to bring the work thoroughly up to date.

The book tells you just what to do, how and when to do it Nothing has been omitted, no detail has been slighted Every part of the automobile, its equipment, accessories, tools, supplies spare parts necessary, etc, have been discussed comprehensively If you are or intend to become a motorist, or are in any way interested in the modern gasoline automobile, this is a book you cannot afford to be without.

THIS BOOK IS SUPERIOR TO ANY TREATISE PUBLISHED
IT IS RIGHT UP-TO-DATE AND COMPLETE IN EVERY DETAIL

Not too Technical for the Layman—Not too Elementary for the More Expert

"The Problem of Our Navy"

A Series of 10 Comprehensive Articles

on the present condition of our Navy, showing its unpreparedness, its present rating among the navies of the world, and what must be done to bring it up to its proper strength and position

Published Consecutively in the Scientific American

Eight articles of this series have appeared in the issues: February 28th, March 7th, March 14th, March 21st, March 28th, April 4th, April 11th and April 18th.

These eight Copies sent to any address in United States for 90 cents in stamps

February 28, No 1—"How the Navy is Daily Employed"—by *Hon. Franklin D. Roosevelt, Asst. Secy. of the Navy.*

March 7, No 2—"Sea Power and Our Foreign Policy."

March 14, No. 3—"The Decline of the United States Navy to Third-Class Rank."

March 21, No. 4—"The Price we Pay for Self-Sufficiency and Unpreparedness."

March 28, No. 5—"Battleship Strength Necessary to Guarantee Peace."

April 4, No 6—"The Shortage of Scouts, Torpedoes and Mines."

April 11, No 7—"The Shortage of Officers and Men."

April 18, No 8—"The Need of a System of Rapid Mobilization."

April 25, The 9th article appears in this issue—"The Need of a Council of National Defense"

The 10th and concluding article written especially for this series

"Making The Navy An Economic Asset"

By HON. JOSEPHUS DANIELS, Secretary of the Navy

MUNN & CO., INC. 361 BROADWAY, NEW YORK

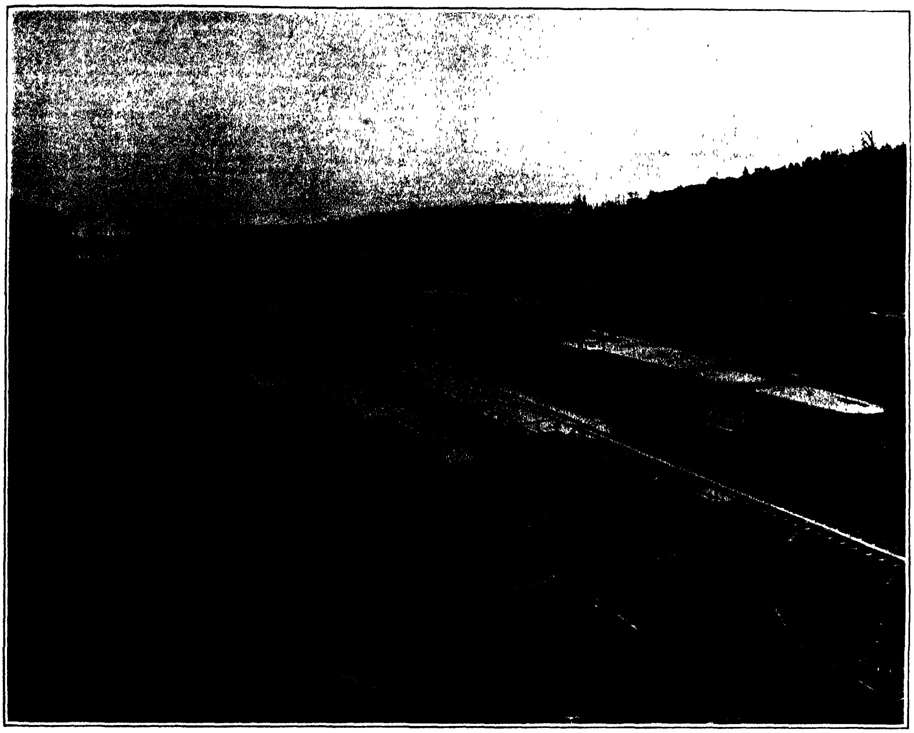
SEVENTIETH YEAR

SCIENTIFIC AMERICAN

VOLUME CX
NUMBER 17.

NEW YORK, APRIL 25, 1914

PRICE 10 CENTS
$3.00 A YEAR



Length, 825 feet; width, 80 feet, inside height, 56 feet Estimated cost, $3,275,000 for the locks and canal

Lake Washington *canal* lock.

The Lake Washington Canal Locks

AN important work now nearing completion is the great locks of the Government canal at Salmon Bay, by means of which shipping will be able to pass from Puget Sound at Seattle to Lakes Washington and Union. The works are so far advanced that the first ship is expected to pass through the waterway early in 1915.

The public mind has been so filled with the story of the construction of the Panama Canal and its great locks at Gatun and elsewhere, that it is apt to overlook the fact that several other works of this character of great magnitude are also being carried out. The Lake Washington canal and locks are a case in point. The lock is 825 feet long, 80 feet wide on the inside and 56 feet high. The walls of concrete are 53 feet in thickness at the bottom and 8 feet at the top. This structure is known as the Big Lock. The Small Lock is 30 feet wide and 160 feet long. The latter is being built for the use of small boats, and, of course, it will result in the saving of much expense, since a large part of the traffic is of such size as not to call for the use of the greater structure.

When the locks are finished the level of Lake Union will be raised to twenty-one feet above the high water mark, and both this lake and Lake Washington with the factories along their shores, of which there are many to-day with the prospect of a great many more in the future, will be in direct water communication with the Pacific. One great advantage of the new works is that since the water in the lakes is fresh, ships will be able to pass through the locks and relieve themselves of barnacles and other marine growths which will drop off from their bottoms, leaving them clean for the next voyage. Also, the canals will have a distinct value to the Navy, whose ships of the medium and smaller sizes - all ships, in fact, except the larger dreadnoughts—will be able to enter the fresh water lakes if emergency or other causes should render it desirable

The first estimate for this work was $2,275,000 for the locks, $1,000,000 for the dredging. The cost of the locks is being paid by the United States Government and that of the canal by the city and county

General Gorgas Honored in England

ON March 23rd, Surgeon-General Gorgas, of the United States Army, lectured in London before the Royal Society of Medicine on his sanitary work in Panama. In the course of his lecture he modestly admitted that if the Americans had known no more in 1904 about the mode or transmission of malaria and yellow fever than was known in 1880, when the French tried to solve the problem of sanitation on the Isthmus, they probably could not have done any better than did the latter. The same night General Gorgas was entertained by the medical profession at dinner at the Savoy Hotel, and on the 24th he received the degree of Doctor of Science, *honoris causa*, at a special convocation held at Oxford University, for his work in rendering the construction of the Panam Canal possible by stamping out yellow and malarial fevers The London *Times* editorially refers to Gen Gorgas as "indisputably the *foremost sanitary officer in the world*," and *one* who "has perhaps done more than any other man to throw *open the tropics, or to show how they can be thrown* open, to habitation by Caucasians."

Motor Omnibus Service for Bolivia. At first blush, the *mountainous portion* of Bolivia would not appear just the place for the establishment of a motor 'bus service. Yet one is to be established there. Four six-cylinder 'buses have been purchased by a syndicate to replace mule-drawn coaches which heretofore have been used. The route is approximately 100 miles in length, and the 'buses must always be operated at an altitude of 7,000 feet or more. The service will link the cities of Potosi and Sucre, which latter is the capital of Bolivia. Leaving the former city, there is a climb of five kilometers where the highest pass in the Andes (14,000 feet elevation) is crossed. The average grade is about 17 per cent. Three of the 'buses will carry 11 passengers each, in addition to a certain amount of freight The fourth is a *de luxe* extra fare car with heavily upholstered seats and accommodations for only seven passengers. All of the cars are electrically lighted and started They will be operated on a regular schedule, making the trip one way in 12 hours.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement

Highway Problem in New York State

THE State of New York is engaged in building twelve thousand miles of road, which, according to Governor Glynn, will wear out forty years *before it is paid for. That is an astounding statement*, and unfortunately it is not more astounding than it is true. This fact and many others of an illuminating and extremely disconcerting character were contained in a recent message of the Governor to the Legislature. The message is written in the direct and unadorned style which characterizes the Governor's utterances, and it contains an array of facts of such great importance to the people of this State, that we could wish to see a copy of this message placed in the hands of every voter throughout the State.

The question of the proper construction and maintenance of roads is not a new one in the columns of this journal. For many years, and during the whole period in which the country, awakened to the sense of its need, has been giving attention to the matter of highway construction, the SCIENTIFIC AMERICAN has emphasized the fact that the problem is more one of maintenance than of construction. The various States have built new macadam roads upon the most approved modern principles, and these roads, at least in late years, have been as good as any that could be constructed. Unfortunately the State authorities have been slow to realize that, of all civil engineering constructions, the macadam road is the one of all others that needs incessant supervision, and immediate and most careful repair whenever and wherever the signs of breaking down and general disintegration are seen.

The macadam road is admirably adapted for the class of highway traffic which passed over it in the period preceding the appearance of the automobile and the motor truck. For horse-drawn traffic it is ideal, and, with a reasonable amount of supervision and repair, it may be regarded as a permanent structure. To-day, however, such are the speeds and weights of the automobile and motor truck, and so greatly have they multiplied in numbers, that the macadam road has proved unequal to the burden laid upon it; for even where the materials are available for treating its surface, the cost of maintenance has reached a figure which renders it an uneconomical construction and invites a search for some other type of road, which will cost no more, or but very little more, to construct, and whose annual repairs bills will be reasonable.

The brick road offers such a substitute. Its first cost is not prohibitive, it is very durable; and the annual cost of repairs under a careful supervision is almost negligible. A substitute whose first cost is less than that of the brick road, but regarding whose cost of upkeep there is less data available, is the concrete road.

Now a first-class macadam road costs in this State from $10,000 to $13,000 a mile to build; a concrete road costs from $12,000 to $16,000 a mile, and a brick road costs from $20,000 to $25,000 a mile. Thus far the experience of the modern road builder with concrete has been limited. Michigan has roads of this character in one county, and the results have been very satisfactory; but the roads have not been in service long enough to justify any conclusion as to their permanence and economy. In hundreds of cities brick roads have been laid and have been down for many years, which, without exception, have demonstrated their durability. Roads of this character, which have been in service for twenty-five years, have stood up under the test of the hardest kind of traffic. What is more to the point is that the annual cost of maintaining these brick roads has been remarkably low, ranging from practically nothing to from $10 to $50 per mile.

Now in New York a mile of macadam costing $12,000 would not last over ten years, and it costs $1,000 a year to maintain and surface such a road. At the end of the ten years the roads must be rebuilt, and the cost of the reconstruction would be $6,000 a mile. The total expenditure for twenty years on a macadam road amounts to $36,000, including $12,000 for building, $18,000 for maintenance, and $6,000 for rebuilding at the end of the first ten years.

Compare this with the total expenditures for ten years on a vitrified brick road, which will amount to $26,000 only, if we allow a maximum of $25,000 a year for building and a maximum figure of $50 a year for maintenance.

Governor Glynn advocates the use of vitrified brick rather than concrete because the State geologist informs him that New York State has an inexhaustible and widely distributed deposit of shale, which may be made the basis of a brick industry large enough to supply all the local requirements with materials of the best quality. The Governor advocates the use of prison labor in making the bricks, leaving the State roads to be constructed by free labor working under contractors or in the employ of the State itself. It is estimated that by this plan brick roads can be constructed at a cost of $15,000 per mile. Now on this basis the total cost of a mile of brick road for twenty years would be $16,000, including $15,000 for the original construction and twenty years of maintenance at $50 a year. The total cost of a macadam road for the same period, as we have shown above, is over double this sum, or $36,000. It is pointed out that the magnitude in the economy thus proposed is shown by the fact that the total saving in 7,300 miles of road yet to be constructed will amount to $146,000,000 in the twenty years after their completion, or more than the total cost of constructing the State's entire system of highways.

That some very radical change must be made in the present plans for the construction of our State highways is shown by the following facts: One hundred million dollars has been voted for the construction of the new highways in New York State. If the future roads cost as much as those which have been built, it will require an additional thirty million to complete *the whole system*. On New York's 12,000 miles of macadam road, the annual cost of maintenance will be $12,000,000. The total cost of the roads will be $130,000,000, and at the end of the ten years, which under heavy automobile and motor traffic is the term of life of a macadam road, the State will have little to show for its expenditure of $250,000,000. Furthermore, in twenty years thereafter the tax for highways will be at least $20,000,000 each year, if the roads are to be kept in proper condition.

"Every year," says Governor Glynn, "the taxpayers of New York will be compelled to pay $20,000,000 for *maintenance*. Every year they will be forced to pay $5,000,000 in interest charges on their bonds. Every year they will be compelled to contribute $2,500,000 to the Sinking Fund to take up the bonds when they mature; and every year they will be required to pay additional millions to rebuild part of the roads on which they are lavishing these tremendous sums. In other words, New York must either change its road policy or prepare to levy a perpetual and yearly road tax of $2 on every man, woman and child within its borders."

The Medical Congress and Our Sewage Scandal

WHAT expressions of disgust and horror were voiced by the distinguished foreign medical men as they sailed into the harbor of this city last week, we have not been informed. But surely they could not have failed to observe that Manhattan is an island surrounded on all sides by sewage. Deluded by the notion that the North, the Harlem, and the East Rivers were really flowing rivers of salt water, and that salt water has an unlimited capacity for digesting sewage, we have been pouring into these bodies of water the excreta of the city for years, without the least concern, until matters have become so serious that it has actually been necessary to dredge out the docks to remove accumulations of sludge.

It requires no critical analysis to reveal the foul conditions of the harbor. The floating refuse is all too evident to the casual observer from the steamship decks, and it must remain a disgrace to the city until adequate methods of sewage disposal are adopted. Fortunately steps in this direction have already been taken. During the administration of Mayor Gaynor a commission of five experts on sewage disposal and engineering was appointed to investigate conditions and to propose remedial measures. After a careful study of the matter, a plan was outlined which we explained in the columns of the SCIENTIFIC AMERICAN about a year ago. It consisted in establishing treatment plants on islands in the East River, and on an artificial island in the lower bay where most of the sewage could be treated to have the solids removed and taken away by tank steamers, while the liquids could be discharged into the surrounding waters after being rendered innocuous. The most spectacular feature of the report was the plan for a tunnel from Manhattan under Brooklyn to an artificial island in the lower bay, and this was dwelt upon to such an extent by the papers as to be considered the chief station of sewage treatment, whereas the plans called for the treatment of twice as much at Ward's Island. Unfortunately, because of its spectacular nature, the plan for an artificial island came to be looked upon as not feasible, even though it involved no departure from well-known engineering practice, and was thoroughly endorsed by competent engineers in addition to the engineers of the Commission. Realizing this, the Commission found it necessary to modify its plans.

A policy of progressive construction is now recommended. It is urged that intercepting sewers be built along the shores of the East River on both sides and that they be led to filter stations, where the sludge will be removed from the sewage and the liquid matter discharged into the river. The sludge would have to be hauled away in tank steamers. This would involve an immediate expenditure of $4,000,000. But it would represent part of the ultimate system as originally outlined by the Commission. When the city was ready to extend the system farther, a tunnel would be run under the river connecting the two intercepting mains, a pumping plant would be built on the Brooklyn side and a tunnel would be run from there through rock to the artificial island in the lower bay. This would involve an expenditure of $18,000,000 more, according to present estimates, while the work already done would fit into the system without requiring any reconstruction or waste of the original outlay. But before this extension was built, the plant at Ward's Island would be installed to relieve conditions in the upper part of the city.

In the mean time possibly some plan may be evolved for utilizing the sludge. The matter has been given serious consideration, but so far no method has been brought forth for utilizing the material, and apparently nothing can be done but to haul it away in tank steamers. Here it seems is a problem for the inventor to solve.

We are pleased to note that the new administration shows an eagerness to take up this pressing problem of sewage disposal. The Mayor and the Board of Estimate are investigating the report of the Commission, and the matter is to be considered further at a second meeting next month. We realize that matters of such great importance must be taken up with due deliberation. But the problem has already received exhaustive study at the hands of a commission of competent engineers, and we cannot but urge that their plans be pursued with all speed.

The Problem of Our Navy

THE series of articles on "The Problem of Our Navy," which has been running consecutively for the past two months in this journal, is now drawing to a close. We cannot forbear drawing attention to the fact that the serious crisis which has developed over night in the Gulf of Mexico is a striking illustration of the necessity of this country's possessing a navy whose ships are prepared to respond instantly to the call of the President, and proceed to any point where it is necessary to make a demonstration of the power of the United States and of its determination to secure for its flag due respect and for its citizens, whether military or civilian, proper treatment.

The last article of the Naval series, written by the Secretary of the Navy, which will appear in our next issue, will deal with an important element of the navy problem under the title: "How to Make the Navy an Economic Asset."

Biological Effects of Blue-violet Rays

THE ordinary data of physical climatology are of limited value when applied to the solution of biological problems. Thus air-temperature is well known to be of much less significance in this connection than direct solar radiation. Moreover, recent studies make it evident that gross solar radiation is less important, biologically, than radiation of particular wave-lengths, especially the blue-violet. H. A. Spoehr has been making comparisons at Tucson, Arizona, between the measurements of solar radiation as a whole, obtained by means of the Smithsonian pyrheliometer, and measurements of blue-violet radiation with an oxalic acid photometer. He finds that the intensity of the latter shows sudden and unpredictable variations quite independent of the variations in total intensity. Winter values are decidedly less than those of summer, while the afternoon is generally weaker than the morning. Reflection from cumulus clouds appears to increase the values.

Engineering

England Prefers Hydraulic Gun-Operating Gear.—Some years ago Great Britain, which has used exclusively hydraulic operating gear for her guns and turrets, made an extensive trial of electrical gear on the battle-cruiser "Invincible." Two different electrical systems were fitted in the barbettes which carried the eight 12-inch guns. It is stated that none of the systems has come up to expectations, and they are now being removed to make way for hydraulic installations.

The Merchant Tonnage of the World.—The latest figures showing the tonnage of the merchant fleets of the principal maritime powers, prove that Great Britain still holds her commanding lead, with a tonnage nearly one third greater than that of all the other maritime powers combined. Thus Great Britain possesses 20,275,791 tons; Germany, 4,998,746; United States, 3,489,736 tons, the greater part of which is domestic shipping; Norway, 2,475,328 tons; France, 2,246,504 tons; Japan, 1,709,062 tons; and Italy, 1,571,761 tons.

The Increasing Size and Speed of Submarines.—The day is approaching when seagoing submarines of high surface-speed will accompany the main fleet on the high seas. Large vessels of this type, of 21 knots speed, have been designed for our Navy. Great Britain is building, in the "Nautilus," the largest submarine in existence, which is intended to be as seaworthy while on the surface as the latest type of destroyer. Its surface speed will be not less than 21 knots and it will have a submerged speed of from 15 to 16 knots; it will carry six torpedo tubes, and the surface displacement will be about 1,500 tons.

A French Sixteen-Gun Dreadnought.—The French naval authorities are so well pleased with their four-gun turrets, that their latest class of dreadnoughts is to be fitted with four of these turrets, carrying among them a broadside of no less than sixteen 13.4-inch guns. These ships will be able to concentrate eight guns ahead and astern, so that in point of numbers their all-round fire will exceed that of our own "Pennsylvania," which can fire six 14-inch guns ahead and astern, and twelve on the broadside. The British in the "Queen Elizabeth" have decreased the number and increased the power of the guns, these ships carrying each eight 15-inch guns.

The Navy and Columbia University.—The Secretary of the Navy has expressed his gratification and pleasure in noting the co-ordination in the Post-Graduate Department of the United States Naval Academy at Columbia University, and the advance made by young naval officers under instructions in the lecture rooms and laboratories of that university. Eighteen officers are taking the course at Columbia, in which the theories of thermodynamics, machine design, electricity and radio-telegraphy are adapted for practical application in the naval service, and in which special subjects and problems that are encountered on board ship are worked out.

Steam Shovel Work Completed in Culebra Cut.—The dry excavation in Culebra Cut was terminated on March 31st, when the three 95-ton steam shovels that were engaged in lessening the pressure on the east Culebra slide north of Gold Hill, were withdrawn and made ready for dismantling. When the steam shovel work was completed on the bottom of the cut in September, 1913, no less than thirteen steam shovels were engaged on high levels at various points of the cut. That number has been gradually reduced. At the end of November six were in service; at the end of December, four. Two more were removed late in February, and now the finishing up at Culebra is being accomplished by dredges.

Canal to Open About July 1st.—Col. Goethals has announced that, unless unforeseen developments occur at the Cucuracha slide, and this is not likely, the canal will be opened to commercial vessels about July 1st of this year. The dredges are working on the channel which has been cut through the slide, and the present effort is to make the channel so broad that these dredges will not interfere with the passing of ships. Incidentally, it may be mentioned that Col. Goethals is opposed to the exemption of tolls "because," as he has said, "I want all the money we can get out of the operation of the canal." He further stated that the fortifications on the Atlantic side of the canal are about completed, and those on the Pacific side about two thirds finished.

Oil Cooking in the Navy.—In agreement with the Navy Department policy of using oil instead of coal, there have been installed on the "Pennsylvania" and on Battleship 39, oil ranges for cooking purposes. In the matter of first cost there is a saving by the use of oil for cooking of about $8,500 for each ship and in operation the economy is much more marked. The question of the economy of operation in the galley is quite important. Thus the batch of bread alone baked each day for the crew of a modern dreadnought calls for the use of about six barrels of flour. The relative costs of cooking by the different methods have been found to be as follows per day: Electric range, $22.50; coal range, $16.00; oil range, $5.65. When in addition to the economy, the cleanliness and absence of ashes is considered, the advantage of cooking by oil on a ship which burns oil only in its main boilers is readily apparent.

Electricity

Submarine Power Cable.—The much-discussed project of an under-sea power line from Sweden to Denmark appears to be on the way to execution, for according to recent reports the two countries have now authorized the laying of the cables, and the work is to be soon begun. The object of the scheme is to make use of water power in the southern part of Sweden, employing the fall of the Lagan River, and to bring this power by under-sea cable to the island of Zeeland, where it can be employed to advantage.

Wireless Telephony.—An Italian engineer, Signor Marzi, has invented a new microphone for use in wireless telephony, so that from Eiffel Tower in Paris it is now possible to hear concerts taking place in Brussels, a distance of about 225 miles. The singing could be distinctly heard, although it was not possible to make out the words of the songs. The well-known musical airs, the "Marseillaise" and the "Brabançonne," were recognized when they were being played on a gramophone 60 miles from Brussels.

Wireless Research Committee.—Under the auspices of the International Wireless Scientific Commission, there has been founded a French scientific committee, whose aim is to originate and facilitate this class of work in France and colonies, first relating to wave propagation; second, measurements in wireless work; third, study of various problems. The committee will be specially occupied with organizing researches which are proposed by the international commission. Seven to eleven active members form this body, with numerous corresponding members, and funds are to come from subsidies or donations. Prof. Branly is honorary president, and M. Blondel active president, while the list includes prominent men such as Abraham, Ferrié, Bethenod and Tissot.

Recording Radio-Telegrams with the Telegraphone.—M. Dosne has invented a method for recording radio-telegrams. He first substitutes for the telephone receiver of wireless telegraphy a sound amplifier and then connects this with the "receiver" of a Poulsen telegraphone. In this manner the microphonic current serving to convey the reinforced sounds arrives with all its variations to a bobbin of fine wire in the center of which is a pen of soft iron in contact with a rotating plate or traveling band of steel. The variations in the magnetization of the soft iron pen leave a sort of magnetic writing on the steel plate which has the property, when it is afterward passed under the iron pen which wrote it, of provoking a repetition of the original signals in the connected telephones.

New Haven Electrification.—Electrification of the New York, New Haven and Hartford Railroad between New York and New Haven will be completed probably by June 1st, as far as the overhead contact and distribution system is concerned. This will provide a continuous electrification of seventy-six miles, of which twelve miles, from Grand Central Station to Woodlawn, belongs to the New York Central. The extent to which the trains will be operated by electricity after that date will depend upon the output of current from the Cos Cob power station. The Cos Cob power plant has been extended to permit of a very large percentage of complete electric service; but it will not permit of a hundred per cent of electric service until power plants have been constructed at the eastern and western extremities of the electrification zone. Owing to heavy expenditures it has been necessary to forego the building of these additional power plants, so that complete electric operation will be delayed for an indefinite period, depending upon the general financial condition of the company and the country.

Berlin's High-Tension Service.—The Berlin central stations have been engaged, during the past, in supplying three-phase current at 6,000 volts or at 220 volts to several localities in the suburbs of towns, but within a recent date there has been made quite an extension in the electric supply system, as the plants decided to furnish current throughout quite a wide region in the surburbs. But the pressure of 6000 volts which was hitherto employed was found to be insufficient for the proposed longer lines, and this led to the adoption of a new standard of 30,000 volts for such work A special network of underground cables was accordingly laid throughout the suburbs. Upon the new plan, three-phase current is furnished by the city station of Oberspree at 30,000 volts. Six cables start from this plant in order to make up two lines of three cables each, and one of these lines covers the northern section of the region, while the other takes in the south. Each line then subdivides into a certain number of sections, in the centers of which there are erected transformer posts in order to afford a step-down from 30,000 volts to 6,000 volts. At this latter voltage, the current is brought to the different localities and is then further transformed from 6,000 to the standard voltage of 220 volts, such as is needed for consumers' use. It is to be noted that underground cables are used for the 6,000-volt as well as the 220-volt lines.

Science

The Solar Eclipse of August 21st.—In the Scientific American of April 4th, it was stated that an eclipse of the sun would occur on April 21st. This was of course a typographical error, as the next eclipse of the sun will occur on August 21st All the matter relating to the next solar eclipse is contained in the American Ephemeris and Nautical Almanac for 1914, and, with the omission of the Besselian Constants, in the American Nautical Almanac.

Within One Degree of Absolute Zero.—In a recent lecture, Kamerlingh Onnes, who has been awarded the Nobel prize for physics, remarked that we can now obtain, experimentally, a temperature which is only removed from the absolute zero of temperature by one degree. The temperature thus obtained is lower by two or three degrees than the temperature of sidereal space, which, according to the calculations of the astrophysicists, is about four degrees above absolute zero

Statistics of the Nobel Prizes.—From 1901 to 1913, sixty Nobel prizes have been awarded. If we class the prizes by countries, comparing the populations, we see that the most favored countries are the three Scandinavian countries: Sweden, Norway and Denmark, which is significant in view of the nationality of the Jury Then come Holland, France with 14 prizes and 39 millions of people; Germany with 18 prizes and 65 millions of people. After these come Switzerland, Belgium and England. Finally the United States and Russia have each received only one prize.

Vacuum Tar.—By distilling coal under a vacuum of 15 millimeters of mercury, Pictet and Bouvier obtain what they style "vacuum tar," this appearing to be quite different from usual coal tar Such tar contains no phenol or aromatic carbides, and when oxidized by permanganate, there are produced acids of the fatty series. The properties of this tar resemble those of Caucasus petroleum, especially constituted by hydro-aromatic carbides These experiments tend to confirm the hypotheses advanced by Berthelot and others as to the formation of the constituents of tar

An International Journal of Vulcanology.—In this age of specialization it is anomalous that the periodical literature relating to volcanoes has heretofore been scattered through a great number of geographical and geological journals, owing to the lack of a journal devoted especially to vulcanology Such a publication has now been founded, under the title *Zeitschrift fur Vulkanologie*, by Dr. Immanuel Friedlander, of Naples, and is issued by D. Reimer, in Berlin It will contain memoirs, abstracts, notes, etc., in German, Italian, French, and English.

Zoological Investigations in Panama.—An excellent opportunity of studying the fauna of the Gatun region of Panama has been afforded by the concentration of the animals in small areas, due to the flooding of the region traversed by the canal. Such investigations are also facilitated by the fact that rivers previously unnavigable can now be ascended for the purpose of collecting specimens. Accordingly Mr George Shiras, 3rd, of Washington, the well-known photographer of wild animals, and Mr H E Anthony, of the American Museum of Natural History, have visited this region, the former to take flash-lights and other photographs, and the latter to make collections

The First Pure Radium Salts Prepared in America.—A chemical manufacturing company of Pittsburgh has just announced its manufacture and sale of the first pure radium salt produced in America Of this amount 133 milligrammes of radium element in the form of anhydrous radium chloride has been sold Since the price is steadily holding to $120,000 a gramme, this is a very respectable start for the new American industry. The salt was extracted from the Colorado carnotite deposits, which are considered by the United States Bureau of Mines to be the largest deposits of radium-bearing ores in the world.

The Criminal Type. Dr. C Goring is the author of an English Blue Book which contains much valuable criminological information Following the suggestion of Dr. Griffiths, deputy medical officer of Parkhurst Prison, a large number of prisoners convicted of certain similar offenses were subjected to accurate measurements in order to ascertain whether these showed any deviation from what may be described as the normal type This material has all been tabulated by Dr. Goring. Like most modern criminologists he makes short shrift of Lombroso's "criminal type" "No evidence has emerged confirming the existence of a physical criminal type such as Lombroso and his disciples have described. . . There is no such thing as a physical criminal type. There is no such thing as a mental criminal type" The eugenists will surely find much confirmation of their theories in Dr. Goring's book "Family incidence of crime is not fortuitously distributed, it is not entirely independent of lineage; criminals do not occur equally in all families of the general community, but tend to be restricted to particular stocks or sections of the community; to those stocks tainted with criminal ancestry."

Stalking wild life with the kinematograph.

Stalking Game With the Kinematograph

How the Film Has Educated Zoologists

By the English Correspondent of the SCIENTIFIC AMERICAN

NATURAL history films have shaken to the foundations many staunchly rooted beliefs concerning animal, bird, and insect life. Not so long ago a film was produced in England which aroused considerable discussion It was unequivocally stamped as a fake, but the kinematographer was able to furnish such conclusive additional proof that the incidents portrayed upon his film were absolutely true to Nature, that he was able to silence his critics The latter then, by pursuing independent investigations along similar lines, were able to ascertain for themselves that what the film illustrated was correct, and that the text books were in error

In order to secure absolute realistic films it is imperative that the pictures should be taken in the field.

In order to prosecute this branch of the kinematographic art extreme ingenuity is imperative The animals, reptiles, and birds are extremely wary and cunning, so that it is difficult to track them to their lairs. Even then inherent timidity has to be overcome so that the subject may be photographed unconsciously In one instance an indefatigable worker spent eight weeks in a stream, immersed to the thighs, in his efforts to kinematograph a particularly chary waterfowl The clicking of the mechanism proved the first stumbling block after an ingenious ambuscade fashioned from a floating tree bough had been established within a yard of the bird's nest Every time the machine commenced to whirr the bird sporting in front of the camera took fright and scurried away In order to overcome this obstacle the operator contrived a novel clockwork mechanism which emitted a noise similar to the moving picture camera, and this he set in motion in close proximity to the wildfowl's home, keeping it running continuously night and day. For the first few days the bird regarded the unwonted noise with intense suspicion, but gradually it became accustomed to the sound until at the end of a fortnight it took no notice of it whatever. Then the operator was able to proceed with his camera without frightening the bird, and as a result secured some pictures which aroused considerable interest, for the simple reason that it was the first occasion upon which this subject had been caught, while many of the incidents which he filmed were quite unknown even to the naturalist

Hedgerow life is particularly exasperating because the smallest birds for the most part are exceptionally shy One operator, in order to secure some pictures concerning one of the smallest of the feathered tribe, cut a passage through a thickset hedge, and by means of a specially contrived tripod, the length of which gave him command of the nest, he was able to film his subject in peace and quietness after he had calmed the bird's suspicions.

In another instance the operator contrived a huge dummy tree trunk with a small living apartment within. It was erected on the verge of a swamp where wild fowl gathered for the nesting season. The operator lives here for some six weeks, the apartment within being fitted up with a camp bedstead, stove, and culinary utensils Movement to and from the "hide" had to be carried out very cautiously, since in this particular instance the birds under observation have the peculiar trait of forsaking their nests, when sitting, at the slightest signs of an interloper's approach.

Extreme patience is a virtue in kinematographing wild life. Climatic conditions create an important part in the quest, while there are the birds' natural foes to be considered. On more than one occasion a half-completed film has been ruined by a tragedy of Nature, so that the whole of the work has to be done again. This applies particularly to wild waterfowl. Water-rats appear to know virtually to the minute when an egg will hatch.

One natural history kinematographer, who makes a study of small feathered forest life, utilizes a somewhat elaborate apparatus A substantial elevated platform is erected, approached by a ladder. Upon this raised platform a small framework covered by canvas is built to house the camera and the operator. But to mislead the denizens of the forest trees the whole is artfully concealed beneath a maze of branches which hide every vestige of the canvas tent, while the rounds and sides of the last are also entwined with creeping plants. In the contrivance of such hides, however, it has been found that the green growth covering the "plant" must be kept in a fresh condition The bird detects withered trees quickly, and its suspicions are aroused.

But probably the most novel "artifice" ever contrived for stalking Nature is the cow that was designed for approaching wild animals in safety. This is made of *papier-maché*, and stands no less than 12 feet in height The carcass is built of a substantial framework so as to withstand hard usage, the skin being represented by the *papier-maché* covering, colored and tinted according to Nature. Within the cow is a platform upon which the operator stands with his camera. Access to the interior of the dummy is afforded by a door in one flank, and through this the operator points his lens, the door being kept open while kinematographing is in progress. The height of the dummy enables the operator to stand erect and to run his instrument in comfort. The animal itself is mounted upon wheels so that it can be maneuvered into position. Should a study happen to observe the operator through the open door, safety is possible by closing the latter immediately, in which event the spring of the beast would be rendered abortive, although it is possible that the impetus of the leap might overturn the dummy, though this is improbable, because the feet of the artifice are heavily weighted.

By means of this device it is possible to approach such wild animals as lions, panthers, leopards, and hyenas in perfect safety. Curiously enough the objects under observation never appear to observe that the stature of the cow is decidedly abnormal. At all events, the operator who uses this dummy confessed to me that although he had approached a ferocious lion within ten feet, the animal never had evinced the slightest doubts concerning its genuine character, but had resumed his movements unconcerned.

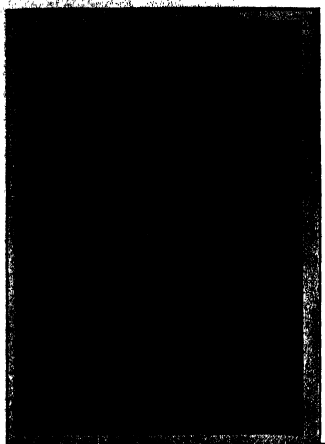
The Problem of Our Navy

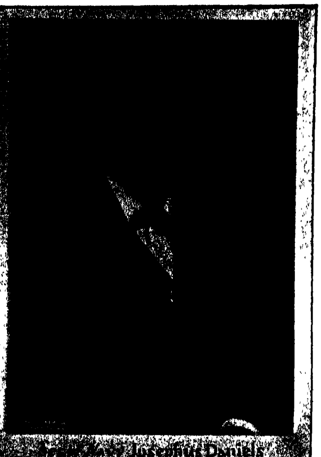
IX.—The Need of a Council of National Defense

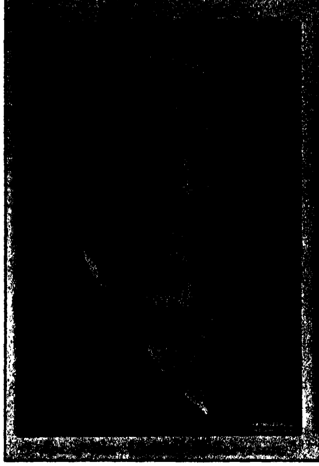
By the Editor

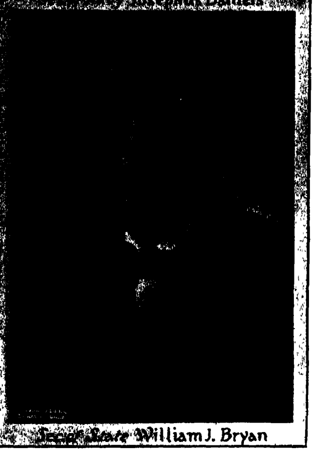
What is needed is the institution of a powerful, broadly representative board, composed of members of the Navy, of the Legislature, and of the Executive, which would consider, from every point of view, this question of naval increase and all naval questions of whatsoever kind, and present its findings to Congress with all the definite governmental authority which such a board would carry.

Illustrated by Photographs, Copyrights by Harris & Ewing









THE EXECUTIVE MEMBERS OF THE COUNCIL OF NATIONAL DEFENSE

OUR study of the problem of the United States Navy, as thus far developed, has revealed the following conditions:

I. The spirit of international aloofness in which the United States had worked out its destiny during the first century of its existence was dissipated by the unforeseen outcome of the Spanish war, whose successful military activities moved our frontiers a thousand miles eastward into the Atlantic and westward five thousand miles to the very doors of Asia. The country, so far *from deploring the new conditions, not only frankly* accepted them, but immediately proceeded, both in its diplomacy and by the increase of its naval and military forces, to make secure its position as a great world power. It reaffirmed, most strongly, the Monroe Doctrine, commenced to build and fortify the Panama Canal, boldly advocated and put through the policy of the Open Door in China, and became in the Pacific the leading exponent of the doctrine of Asiatic exclusion. Contemporaneously with this great enlargement of its foreign policies, the United States made haste to provide the *means for their enforcement*, building up its navy so rapidly, that, within half a dozen years, it had become the second naval power in the world.

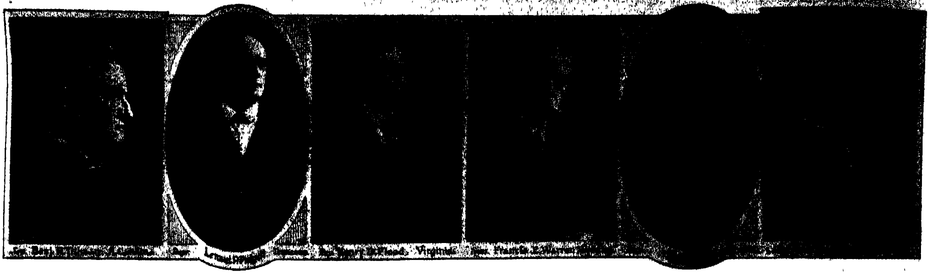
II. In the year 1905, when we had reached the zenith of our diplomatic influence and naval power, the appearance of the dreadnought produced a revolution in the rating of naval strength and threw our twenty-three first-class battleships into the second line. At this very time, when other nations began to accelerate their naval construction, building upon dreadnought lines, the United States, with that fatal lack of continuity of plan and purpose for which it has paid so dearly in years gone by, began to slacken its activities—the falling off being shown by the fact that whereas, from the Spanish war of 1898 to 1905, we had built an average of four armored ships per year, from 1905 to the present time, during the dreadnought era, we have built at the rate of only one and a half armored ships per year. As the result of this neglect, we have sunk to the position of a third rate naval power, there being one first rate power, Great Britain, with 42 dreadnoughts; *one second rate power*, Germany, with 26 dreadnoughts; and three third rate powers, the United States with 12, France with 11, and Japan with 10 dreadnoughts built and building.

III. The gravity of the present situation is aggravated by the fact that, during the period of decline of our navy in relative strength, we have asserted our ambitious foreign policies with a definiteness and in an uncompromising spirit, *for which no parallel can be* found in all the history of the republic.

IV. The failure of the people of the United States and their representatives in Congress to maintain a navy commensurate with the growing wealth of the country and the stupendous foreign policies to which it has so boldly committed itself, is due largely to the mistaken belief that the vast but undeveloped resources of the country, as regards both the men and of the materials of warfare, are a sufficient guarantee of peace—and this in spite of the fact that this very policy of unpreparedness has saddled the country with an annual pension roll of $180,000,000. Prudence demands that, as quickly as possible, our navy shall be restored to the position of second in rank which it held in 1906 To effect this our private and public shipbuilding yards should be employed to their fullest capacity, until our dreadnought line is sufficiently powerful to restore us to the second rank. The appropriation by Congress of a sum equal to that which has this year been appropriated for pensions, if spread over the next three years, would give us a first fighting line by the year 1920 which would be sufficient to preserve the peace by discouraging any conflict for the possession of the Caribbean and the control of the Panama Canal

V. Contemporaneously with the upbuilding of our first fighting line, it should be the care of Congress to make good other most serious deficiencies in the navy. The interference with and neglect by Congress of the carefully-thought-out plans of its naval advisers has led to a situation, in which we find ourselves with only three scouts when we should have thirty, with only a little over one round of torpedoes for our torpedo tubes when we should have ten rounds, and with practically no mines or mining outfits The serious nature of this deficiency is seen, when we bear in mind that the torpedo and the mine caused the loss of more ships in the Russo-Japanese war than were wrecked or sunk by gun fire.

VI. Although the fighting ships of the American Navy in their several classes are, date for date, fully equal to the best in the foreign navies, they are severely handicapped by the shortage in the personnel Of the officers and the men themselves, it may be said that there are none more efficient in any of the navies of



THE LEGISLATIVE MEMBERS OF THE COUNCIL

the world. It is in quantity, not in quality, that the ships and their personnel are deficient. In the crisis of a suddenly precipitated war, it would be impossible to man even our first fighting line with its full complement of officers and men, without robbing the reserve fleet of that nucleus of a trained force which is necessary to render it efficient Because of an obsolete method of promotion, our officers will reach command and flag rank long after they have passed that period of their lives when they would have been most efficient for the duties of these particular ranks. The remedy is to be found in a method of selection by which the most efficient officers will be chosen for promotion, those not selected being relegated to the reserve list and shore duty. To insure that the number of officers and men shall bear a strict relation to the number of ships in the fleet, the increase in the personnel should be made annually, and it should bear an exact proportion to the yearly increase of the fleet, as determined by Congress

VII. No navy can be efficient if it is not possessed of a carefully-worked-out plan of mobilization. The lack of any such plan constitutes one of the greatest weaknesses of the United States Navy to-day. A perfected mobilization implies the possession of war plans to meet all possible conditions; a personnel sufficient to command the reserve ships and auxiliaries; a large reserve of ammunition, supplies, guns, torpedoes, and coal, a full list of suitable merchant ships assigned to various ports at which they can be transformed for auxiliary service, contracts made with the owners for chartering the ships, and the possession of plans and the materials for the quick conversion of these ships to war purposes; naval stations and bases fully supplied and equipped for rapidly executing the emergency work which would have to be done on a declaration of war; advance bases, with their outfits, materials, and men ready to be transported for duty with the least possible delay; and, finally, a trained naval reserve, composed of ex-enlisted men of the navy, from which the necessary forces may be speedily sent to the coast, for manning the reserves and auxiliaries

The Cause of Our Unpreparedness.

From the foregoing it will be evident that, *although our ships and the officers and men who man them are absolutely first-class, our navy is in a chronic state of unpreparedness for war, and in saying this we wish to emphasize most strongly the fact that the blame for this unpreparedness is not to be laid upon the Navy Department* All the defects which we have mentioned and others to which we have had no time or space to refer, have been long known and greatly deplored within the Department itself. Year after year our Naval Board, which is charged with the work of deciding what the strength and composition of the navy should be, has presented to Congress a carefully-thought-out plan or programme of construction and enlargement. And year by year the programmes have been cut down and mutilated; urgently needed reforms, calling for legislative action, have been refused; and, as a result, we find ourselves to-day with a navy that is not only inadequate in numbers and strength, but the various parts whereof bear no proper relation to each other or to the whole.

Upon whose shoulders then is the responsibility for these conditions to be placed? *It is chargeable to the people of the country at large and to their representatives in Congress. So far as the former are concerned, the neglect of the navy is due either to lack of understanding, or to indifference, or to both. So far as Congress is concerned, the neglect of the navy is due to politics and the disposition of Congressmen to place local considerations and personal ambitions above questions of prime national importance.*

So far as the public is concerned, the ignorance as to the purpose and meaning of the navy can be removed only by the institution of a systematic course of instruction. This should begin in the public and high schools, whose curriculum should include the mastery of a simple primer on political economy, one chapter at least of which should be devoted to the naval and military forces of the country, in which it should be shown why these are necessary and in what proportions. If this were done, the youth of the country would grow up with the conviction that an adequate army and navy is as necessary to the national well being as the provision of a currency and a banking system.

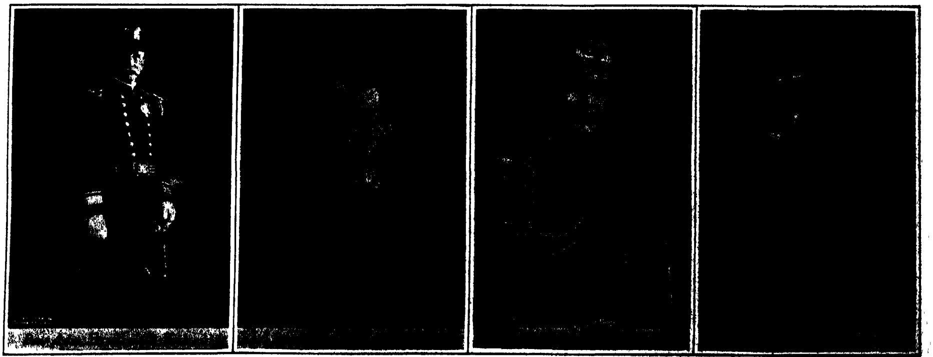
They would understand that the primary purpose of their country's naval and military forces is the same as that of a police force—the protection of the lives and property of the citizens. They would understand that the object of an army and navy is essentially pacific—that it aims to preserve the peace, not to stir up war. They would understand that, just as the 5,000,000 citizens of a great municipality like New York can go about their daily labors and sleep securely in their beds at night, only because of the strength and vigilance of a police force of 10,000 men, so the 100,000,000 citizens of this great country, its enormous wealth, and its far-reaching international interests, can be rendered secure, only so long as the country possesses an army and navy adequate for their protection.

With such tuition in the schools, the youth of the country will pass on into the broader knowledge of full manhood, with a clean-cut understanding of the need, not only for a navy, but for a navy measuring up to its multitudinous responsibilities.

The work of the schools in promoting right thinking might be, and certainly should be, supplemented by the intelligent criticism of the press. To-day such criticism is altogether too one-sided. It deals too largely in superlative approval, and tends to keep alive that feeling of national invincibility, based upon the successes of a hundred years ago, which has much to do with the present indifference to the navy, or rather indifference to the need for its enlargement. In Germany they do these things better. The children in the public schools, and the public at large through the press, have been so well instructed that they understand perfectly well what is the policy of the Government in naval affairs. Hence, the German people, by a very large majority, are thoroughly in sympathy with the naval programme. It should be so with us, and *if every important daily paper and weekly and monthly magazine maintained on its staff a naval expert, who was at all times closely in touch with the naval situation, and whose duty it was to record the absolute truth, failures as well as successes, the people of this country would have such an intelligent and sympathetic understanding of the problem, that the cheap diatribes of a Senator Burton, with his sneers at the "paid idleness" of the navy, would be received with the amused contempt which they deserve.*

So far as the relation of the Government to the navy is concerned, the present unsatisfactory conditions which have led to the decline of the navy in a few years' time to the third rank, are due chiefly to the lack of proper and intelligent co-ordination between the Executive as represented by the President and his Cabinet, the Legislature as represented by the two houses of Congress, and the Navy Department as represented by the technical advisers of the Secretary.

As matters now stand, the technical advisers as represented by the Navy Board draw up every year a programme of construction, representing the minimum requirements. This is presented to the Secretary, who, more often than not, makes a considerable reduction in the number of vessels asked for. The emasculated programme then goes over to the House, where it is subjected to more or less hostile criticism by the House Naval Committee, and by the time it is framed up into a bill, the programme usually has suffered further depletion. Then comes the debate on the bill in the House



THE ARMY AND NAVY MEMBERS OF THE COUNCIL of [illegible] and the usual fight between the so-called [illegible] and "little navy" factions. Too often the arguments against the granting of what little is left of the original minimum requirements of the navy, as advised by its technical advisers, are presented by men who have never given that thoughtful consideration to the subject which its importance demands. Local politics and party politics, which surely should have nothing whatever to do with a subject affecting the very existence of the nation, enter largely into these discussions. The vital issues, such as the relation of the navy to the national policies of the country, seem to be totally lost sight of. The attitude, both in the committees and on the floor of the House and the Senate, would sometimes seem to be one of positive hostility. Too often the suggestions of the Naval Board are treated as though they were requests for something of a personal or privileged character—as though the officers of the navy were trying to get from Congress something which would be for their own benefit.

A Council of National Defense.

What is needed is the institution of a powerful, broadly representative board, composed of members of the navy, of the legislature and of the executive, which would consider, from every point of view, this question of naval increase and all naval questions of whatsoever kind, and present its findings to Congress with all the definite governmental authority which such a board would carry.

With this object in view there is a bill before Congress for establishing what is to be known as "A Council of National Defense." We alone, among the leading powers, are without any such Council, and it is our belief that the present unsatisfactory condition of our naval and military forces is due very largely to the lack of such a body.

It has been said truly by one of our leading naval authorities, that "at present it seems to be the popular idea that the statesmen are in control up to and including the time that the solution of difficulties between nations is impossible except by resort to arms; that after that they call in the naval and military forces to cut the Gordian knot which they have been unable to disentangle, and that the making of war has little connection with the cause of war."

As matters now stand there is a lack of co-ordination, or perhaps it would be nearer the truth to say, a lack of proper means for co-ordination between the Executive, the Legislature, and the Naval and Military Departments; and the object of the creation of a Council of National Defense is to provide the proper means for this co-ordination, not merely at the threat of war or during its continuance, but permanently. If such a Council were in existence, its recommendations to Congress would be free from any suspicion of partisanship or individual departmental influence. It would be authoritative in the highest degree, and it would represent the matured opinion of the Government as a whole.

Such a Council would consist of the President of the United States, who would be *ex-officio* president of the Council, and the Secretary of State, who would preside in the absence of the President. Through the Secretary of State would be represented those broad policies of the nation to which reference has been made so frequently in the present series of articles. It would be the duty of the Secretary to keep the Council informed as to changes and extensions of our policies. Because of his intimate knowledge of the diplomatic situation, he would be able to give early forewarning of the direction from which possible complications might come. For similar reasons, the Council would include the chairman of the Committee on Foreign Relations, both of the House and of the Senate. The financial side of the problem would be represented by the Secretary of the Treasury. Technical information as to the naval and military forces which would be necessary to maintain our policies would be afforded, for the army by the Secretary, the Chief of Staff, and the president of the Army War College, and for the navy by the Secretary, the Naval Aid for Operations, and the president of the Naval War College. The legislative side would be further represented by the chairmen of the House and Senate Naval and Military Committees.

In such a Council of National Defense, the nation would possess a body of men, who, because they were in possession of full knowledge on every side of the great questions involved, would be able to discuss the matter of national defense with intelligence and authority. The plans and operations of the army and navy would be thoroughly co-ordinated, and the upbuilding and maintenance and effective use of our naval and military forces would be conducted on the highest plane of efficiency.

* * * * * * * * * * *

At the present writing the American fleet is steaming to a Mexican port to enforce the demand of the President for a salute of twenty-one guns as an apology for an insult to the American flag.

The crisis thus precipitated may bring the apology demanded—or war.

Herein is presented an object lesson on the facts and principles upon which we have dwelt in the present series of articles on "The Problem of Our Navy"—a confirmation of the need of this country's possessing a navy for the swift enforcement of its policies.

To convince the American people that we need, not only a navy, but a navy adequate to meet all possible conditions, we ask: "If the arrest of our sailors had occurred at Kiel, would Admiral Mayo have sent his ultimatum, and would our fleet be now converging on that port in its full strength?"

The Man at the Switchboard

By Henry Harrison Suplee

IT is one of the greatest claims of applied science to recognition that it is continually acting to liberate mankind from the burden of physical labor, by substituting manufactured power for the effort of muscular energy. The workman of to-day, in very many instances, uses his head far more than his hands, directing and controlling forces generated, transmitted, distributed, and applied with a minimum of exertion.

Formerly the great workshop contained an "army" of laborers, and in many cases this is yet the fact, but the proportion of men to the output is growing continually smaller, and in certain departments of industry, notably in the iron and steel manufacture, and even more in the great power houses, the small number of men, compared with conditions a few decades ago, is remarkable.

The layman, visiting the power-generating station of some important transportation system, such as that of the New York subway, or the Brooklyn Rapid Transit system, is impressed with an almost uncanny feeling that all this powerful machinery is running itself.

It is true that a few men are seen moving quietly about, but these are apparently engaged rather in watching the smoothly running engines and purring dynamos, than in any way exerting themselves to produce any immediate results. Outside, coal is being raised from barges by the edge of the river and delivered automatically to bins in the upper portions of the great building. Within, there is a quiet flow of fuel downward from these same bins into the hoppers of automatic stokers beneath long batteries of steam boilers. The grimy coal passers and perspiring stokers of the old-time boiler house are nowhere to be seen, and in their places there are a few quiet, clean men, with keen, intelligent faces, making an occasional adjustment, or glancing through an inconspicuous peephole.

Beneath the boilers the cinders and ash are being cleared away by conveyors and delivered directly to the cars by which they are removed; no back-breaking shoveling is visible anywhere. Dust, dirt, cinders, all are conspicuous by their absence, and a modern boiler room is cleaner than an old-time machine shop. The engine room, if we may use such a commonplace term to describe the magnificent hall in which the energy liberated from the burned coal is transformed through the medium of expanding steam into mechanical power and on into electrical current, is almost as bare of human occupants as was the boiler room. By careful examination a few men may be seen passing from one machine to another, not working at all in the former meaning of the term, but showing scarcely more than a casual interest, so far as the ordinary visitor might observe. The windows of the great room are bright and free from dust; the mosaic floor might well be the entrance to some modern hotel or museum, the polished hand rail might belong to the companionway of the latest floating palace of the north Atlantic. Overhead, just beneath the chords of the trusses which support the roof and permit the space beneath to be clear of pillars or other supports, may be seen the deep girders of a powerful traveling crane, deriving its power by the consumption of a trifling portion of the current generated by the whirling rotors beneath, and ready at any moment to lift anything, from a few pounds to many tons and deliver its burden anywhere on the floor below. When it is needed its full power may be directed by the effort of one man with less exertion of the wrist than is required of a player on the violin. There is no need for a gang of laborers here.

The commander of a great ocean liner has his station upon the "bridge," whence he may see all and direct everything. The commander of the great power station has also his bridge, but he needs no lookouts to signal to him, he has no need to peer through some enveloping fog to discover the approaching iceberg. The man at the switchboard has before him the quivering needles of sensitive instruments, keeping him apprised of the condition of all that is going on throughout the highly organized system committed to his care, not only within the power house, but out upon the line, and throughout the whole combination of mechanism and forces. He has no need to work hard with his hands, the control is dependent, not upon physical effort, but upon directive movements easily made and immediately effective. The switchboard is the brain of the entire system, directing the energy of the station both within the limits of the building and without, so far as the lines extend.

In such a power station we may find 100,000 horsepower generated, directed, and controlled by a force of fewer than 100 men, and these are none of them working with any serious physical effort, but using their trained minds and skilled hands to the production of far more value than could possibly be conceived under the old idea of productive labor.

When Tredgold formulated his famous definition of the work of the engineer as the "art of *directing* the great sources of power in Nature to the use and convenience of man," it is hard to believe that he did not have before him some revelation of the man at the switchboard in the modern power house.

Fatal Industrial Accidents in Massachusetts

AN interesting table, printed below, has been prepared by the Industrial Accident Board of Massachusetts to show the causes of fatal accidents reported to the commission in its recently concluded first year of existence. The total number of non fatal accidents in the State was 80,694, or about one for every ten wage-workers. The board is of the opinion that at least half of these can be prevented through improved inspection methods, by safeguarding machines before they leave the factory, by the maintenance of safety museums, through lectures, moving pictures, school talks and the elimination of danger spots in plants. There were 474 fatal accidents, classified as follows:

Railroad equipment	119	Machinery peculiar to special industries	7
Falls	66	Belting	6
Vehicles	43	Infection from trivial cuts, burns, etc	5
Hand labor	37	Saws	4
Elevators	33	Explosions (not boiler)	4
Electricity	25	Hoists	4
Street Railways	20	Illness	3
Boiler explosions and burns	15	Presses	2
Excavating	14	Gears	2
Cranes	11	Emery wheels	2
Miscellaneous	11	Occupational diseases	2
Asphyxiation, drowning, etc	10	Glass	1
Animals, insects, etc	9	Wood molders	1
Shafting, set screws, etc.	9	Assault and fighting	1
Falling material	8		
		Total	474

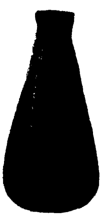
Atmospheric Electricity and Plants

A COMMON experiment to demonstrate the supposed stimulating effect of atmospheric electricity upon the growth of plants consists in covering certain plants with a metallic cage, when it is found that their development is retarded as compared with that of plants not similarly treated, the assumption being that the insulation of the plants from atmospheric electricity accounts for the difference. As experiments of this character have been prominent in the history of electroculture, much interest attaches to observations recently made by P. Lesage on the growth of species of cress and of *Datura tatula*. Plants were grown under a wire cage, as above mentioned, and also under a silk cage of exactly similar dimensions. At the end of three months it was found that the plants under the two cages had been retarded in growth to the same extent, as compared with plants grown in the open air. This result eliminates atmospheric electricity from the problem, and some other factor must be sought. It is found in the obstruction offered by both cages to evaporation. The rate was decreased by the cages 10 per cent in still air and about 30 per cent in moving air.

The Current Supplement

AN article "Machine Tools and the Motor Car Industry" in this week's SCIENTIFIC AMERICAN SUPPLEMENT describes several interesting machines used in the manufacture of automobiles.—B. J. Newman, writing on colossal waste, due to bad municipal engineering, shows how a false economy in dwelling space is paid for by the sacrifice of countless human lives.—Sir Joseph J. Thomson has recently delivered a course of lectures on Recent Advances in Physical Science. The first of these, which appears in this issue, is devoted to a new theory of chemical affinity, which seems destined to solve many problems of long standing and fundamental importance.—Alexander Del Mar contributes an article on the evolution of the breech loader.—C. H. Claudy gives an illustrated discussion of the practical problem of taking a snapshot photograph at the exact moment when a moving object, such as a tennis ball, reaches a particular position, e. g., just as it takes the racket.—Dr. O. Damm writes on blood pigment and chlorophyll in the light of modern investigation.—The principal exhibits at the Olympia Aero Show (London) are illustrated and described.

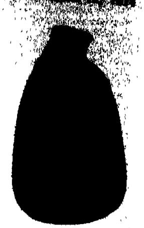
Some Interesting Wiles of the Art Faker



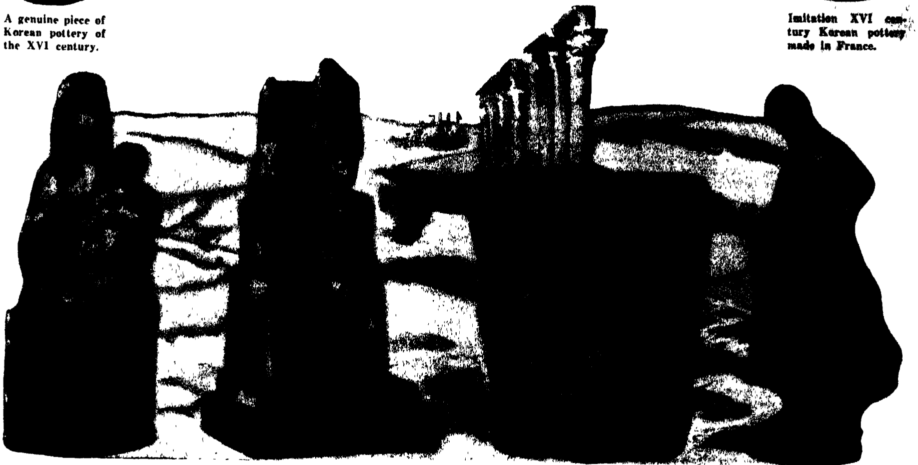
A genuine piece of Korean pottery of the XVI century.

How Patinas Are Produced to Fool the Unwary, How Old Wooden Carvings Are Produced That Would Deceive Even the Craftsman of the Middle Ages, and How the Work of the Old Potters is Reproduced for the Antique Market

By the Paris Correspondent of the SCIENTIFIC AMERICAN



Imitation XVI century Korean pottery made in France.



A Virgin Mary carved in old wood, painted, cleaned with alkali, and finally repainted. Plaster scalings have been used to heighten the deception.

An Egyptian statuette made by taking a cast from an original. The joint between the two halves is visible. An artificial coat of verdigris has been given to the object. A healthy industry in making such "antiques" thrives in Egypt.

A false keystone of modern manufacture, which has been so admirably aged that it is almost sure to deceive the enthusiastic lover of antiques. Only one familiar with methods of faking could discover the fraud.

A false Tanagra figurine made of plaster and cleverly painted. Because Tanagra figurines are in great demand there is a flourishing European industry supplying the market.

M. EMILE-BAYARD, inspector in the Ministry of Beaux-Arts, has recently published an interesting book on the "Art of Detecting Fraud," which reveals many of the technical methods employed by dealers in fraudulent antiquities. Since Americans are large buyers of old art objects, the following excerpts from his valuable work may prove helpful.

For making imitations of ancient sculpture in wood, especially of the middle ages, which were often painted, there are employed either single pieces of heavy timber or an assemblage in the case of very large work. Several pieces are assembled by the use of glue, old rusty nails or wood pins. The appearance of a painted statue is often imitated, and in this case the statue is first painted, and when dry the paint is removed, for the most part by caustic potash. Traces of color which remain in the veins of the wood or in hollow places serve to give the illusion of a statue whose color has faded, an effect which is heightened by touching up the object with gold here and there. This kind of fraud easily passes muster, for the seller of the object tells how he found it in a remote country place, and much covered with dirt, so that in order to clean it at all he was obliged take the color off with alkali. Aging of wood is often done by leaving it in a bath of acid, and when thus treated, the soft parts of the wood sink, and the fibers become prominent. Thus the appearance of age is imparted.

In treating wood in order to give it the appearance of age a warm tone is obtained by the use of walnut stain more or less diluted, depending on whether merely a mellow tone or a distinct brown color is to be obtained, then giving a wax polish by a cloth or soft brush. Unpainted wooden statues are oftenest treated in this way, and a brilliant finish is the result. The hollows are neatly filled with dust, and clumsy and evident repairs are often made in order to attract attention, and make it appear more certain that the piece is genuine. However, time gives to old wood a velvet finish which is inimitable, and by a little practice one can detect this by passing the hand over the surface. Attempts are made to imitate this finish by beating the objects, especially if they are of oak, with a thong or even something harder to reduce the angles and to close up the fibers of the wood, also to produce the effects of injury, knocks, and all the usage of time. But neither these methods, nor the patient use of sandpaper and wax polish, will give to a full degree the polish possessed by old wood, although the inexperienced fail to see the difference.

The use of the saw was unknown in old days. The hatchet was in favor. Any grooves or marks due to a circular or band saw can at once be detected, and as wood was not economized in those days, thin wood should be suspected. Old wood was assembled with wood pins as a general rule, and was not glued and rarely nailed. It is often stated that worm holes are made in wood by firing small shot into it, but that may be doubted. Worm holes can easily be made by suitable tools. Wood can be rotted by burying it in the ground, then watering the ground with acid, although the process is limited, of course, to small pieces, either of wood, stone, or metal.

A supposedly old ivory carving which has deceived a connoisseur.

Patina upon copper is produced in various ways, one of these being a treatment with sulphur vapors, which often gives agreeable iris hues. Oxidation is produced by the use of a mixture of salt and ammonia, the metal being also attacked if need be by acids such as hydrochloric or sulphuric. Metal surfaces are aged by a mixture of lampblack and turpentine, which collects in the hollows of the relief, but a more permanent treatment consists in first applying a coat of black varnish and then rubbing up the metal so as to leave the black parts only in the hollows. A patina is given to tin simply by rubbing it with garlic, or, in other cases, by the use of lampblack, but more striking effects are produced with antimony butter, more or less diluted with water, according to the degree of aging desired. Gold and silver are easily aged by applying bisulphide of carbon.

Another class of work frequently employed on metal objects is that of "embellishing" copper and pewter mugs and pitchers. Plates and the like are given extra ornaments either by *repoussé* or by engraving, so as to be much enriched. Such frauds are difficult to detect, for the object as a whole is authentic. But the added features can often be detected by examining the freshness of the cutting and tool strokes, also the color of the patina. A lack of taste in such ornaments is often evident. As regards silverware, the hall-marks or other goldsmith's marks are now imitated upon goblets or teapots, or ornaments are often added to authentic pieces. In some cases a vessel is made authentic to all appearances by using simply a real bottom piece bearing the hall-mark, and fixing it to a new vessel so that the whole appears to be ancient. Making new pieces by molding is a frequent practice, but here the hall-mark being molded and not punched is much less sharp, and the process can be detected. Great numbers of pieces are made by molding. Thus spoons are transformed into forks which are most needed in silver services, without touching the hall-mark.

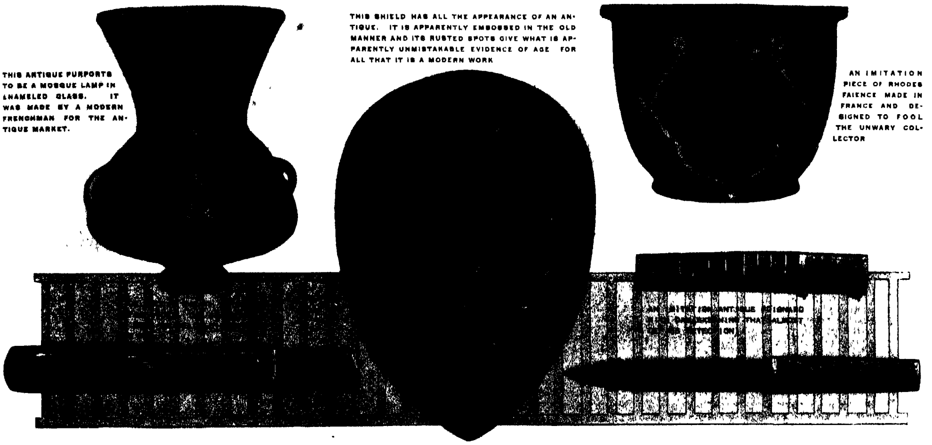
Ancient coins and medals are of course the easiest to imitate, and they are produced in quantities by electrotypers and die workers. By the galvanoplastic process an ancient medal can be reproduced with ease, and it only remains to put on a patina, to gild, oxidise, age with varnish, and the like. Another plan is to saw medals in two and use the most attractive halves, which are then brazed or soldered together. Letters or any kind of signs can be added to increase the interest of the piece, suppressing useless letters by filing them off, and in their place the new letters or signs are struck on by the use of dies. Other practices are to dip the coin in an acid which attacks the relief and changes its appearance, making it more difficult to identify frauds. For all that, the fraud can sometimes be detected, for in the first place the ancient medals were coined and not molded. Attention should be given to mold joints, which are unmistakable signs of spuriousness. In assembling pieces, the harmony of the letters on obverse and reverse should be noticed, also the unity of the field and the border, and the patina. Weighing two medals in the hand, one coined and the other molded, for equal size the cast medal is a little heavier than the other. Filing of the mold edge can often be detected in such work. As to false patina, verdigris will hardly resist the action of lemon juice, which bares the copper, and boiling water removes any varnish or other aging substances, while the real patina given by time will stand the test.

The great demand for ancient armor, which is so largely used for decorative purposes, for instance in panoplies, has given rise to a correspondingly abundant supply, consisting of shields, swords, daggers, battle-axes, and the like. It should be remembered that armor and weapons are, of course, of steel and are forged, the metal being worked by the hammer and also embossed, and each piece is assembled by riveting. If the specimens are made of iron and not steel, the fraud is apparent at once, and all pieces obtained by casting are, of course, false. Soldering or brazing was not employed at that time, at least in the great majority of cases. To increase its strength and flexibility, ancient armor was made of two pieces of sheet, fire softened and beaten together so as to weld them. Ancient helmets are made of one piece, and only the visors are added. Patina is given to iron by burying it for rusting or by sprinkling it with water or acids Exposure to weather is also resorted to, or else the piece is dipped in hydrochloric acid. In these different ways there are obtained alterations which give the appearance of age. Genuine black patina is imitated by a proper use of black varnish, which is then almost entirely rubbed off, and for imitation antique glaives in bronze, verdigris is produced by means of salt, moistened with vinegar or lemon juice. Friction upon metal, or sandpaper, is the enemy of such surface patina. Black rust is, however, often used to conceal soldering or brazing which would otherwise be visible.

The remarkable polish of ancient arms is imitated by patient rubbing with a soft cloth wet with encaustic wax prepared with gasoline (floor-wax), but an experienced eye can readily distinguish between such polish and the real one seen upon ancient steel arms. Damaskeening of arms and armor is imitated or rather supplanted by a process which is easier to carry out. In the real work, grooves are engraved in the metal by tool and then gold or silver wire is laid in; but in the other case the design is simply etched out by acids and gold in fragments or gold leaf is put in and hammered, then filed off to the level of the surface. It is easy to detect by lifting the end of the gold wire by a pointed tool, so as to draw out the continuous wire from the whole design, while in the second case only metal fragments are found. A ready imitation is to gild or silver the whole surface by the use of the plating bath, then protecting the design by varnish and dissolving off the rest of the metal, finishing by a few retouches with the chisel to complete the illusion.

To detect frauds in ceramics is most difficult. Well known potteries often imitated one another's pieces. For instance, the Rouen products were copied at Quimper, Lille, Nevers in France, and also at Anspach and Pavia, while the Nevers works imitated the Italian products from Savona, Urbino, and Faenza, and so on, so that all is confusion. Even the experts cannot find their way. Counterfeits of Bernard Palissy can be detected by noticing marks of the potter's wheel, for the real pieces were shaped by hand, being also reproduced in small number by molding. Tanagra statuettes are as innumerable as Roman lamps, but the former, at least, may rather be called reproductions, for anyone at all familiar with museum specimens can detect them on sight, that is, the ones which are commonly sold cheap, and which are made of plaster and modeled upon a frame backing, then painted and coated with a grainy material, with traces of color or gilding. The real Tanagras were made from molds, and the fineness of their details has rarely been imitated.

Old ivory boxes, statuettes, Gothic diptics, crucifixes, handles of arms, are now produced in great quantities to meet with the demand. Special composition material or modern ivory is employed, with a suitable patina to imitate age. Cracks are made by dipping in boiling water and holding to hot fire, thus producing expansion and cracking, and a mellow hue is given by fumigations of tobacco, tanbark or wet hay A bath of ocher, rubbing with turpentine and Judaea bitumen, licorice juice or lampblack, are all employed. Round shapes can often be detected by noticing the circular marks of the lathe, for instance on a box bottom, and various patinas can be washed off with alcohol or even water. Celluloid is sometimes employed for this purpose.



THIS ANTIQUE PURPORTS TO BE A MOSQUE LAMP IN ENAMELED GLASS. IT WAS MADE BY A MODERN FRENCHMAN FOR THE ANTIQUE MARKET.

THIS SHIELD HAS ALL THE APPEARANCE OF AN ANTIQUE. IT IS APPARENTLY EMBOSSED IN THE OLD MANNER AND ITS RUSTED SPOTS GIVE WHAT IS APPARENTLY UNMISTAKABLE EVIDENCE OF AGE FOR ALL THAT IT IS A MODERN WORK

Antarctic Meteorology

THE meteorology of the Antarctic was altogether enigmatical a little over a decade ago. To-day the observations of the numerous recent expeditions are beginning to make clear its principal features, though much work in this line remains to be done. The most comprehensive summary of the subject is that published by Prof. W. Meinardus in the January number of the *Geographische Zeitschrift*. Series of meteorological observations have now been made at three fixed stations in West Antarctica (the Swedish station at Snow Hill, 1902-03; French station at Port Charcot, 1904-05; French station on Petermann Island, 1909), and at five in East Antarctica ("Southern Cross" station at Cape Adare, 1899-1900; 'Gauss" station, Kaiser Wilhelm Land, 1902-03; English stations at MacMurdo Sound, 1902-04, 1908-09, and 1911-13; Norwegian station "Framheim," 1912-13; Australian station in Adélie Land, 1912-14). All of these lie on the coast, the most southerly being "Framheim," which was over 800 miles from the pole. From the interior we have only the relatively unsatisfactory observations made by sledging parties. To a third class belong the observations made on vessels drifting slowly in the ice, as in the "Belgica," "Scotia," and "Deutschland" expeditions. Lastly, some of the latest Antarctic expeditions have secured numerous observations of the upper air with the aid of kites and balloons. The most remarkable series of such observations was that made by Lieut Filchner's meteorologist, Dr Barkow, who carried out no less than 255 flights on 200 days during the ice-drift of the expedition in Weddell Sea On one occasion a pilot-balloon was sent to an estimated altitude of 56,430 feet, or about 10.7 miles. Much knowledge of the upper air currents has also been obtained from observations of clouds The Antarctic has surprisingly cold summers Roughly speaking, the warmest month in the year has a mean temperature of 32 deg Fahr (the freezing-point) or below everywhere inside the Antarctic Circle, in spite of the continuous sunshine of that season, while in the neighborhood of the pole at the same season the temperature may fall to about 60 deg. below zero Fahr.; an intensity of cold that can hardly be explained merely by the altitude of the Antarctic plateau, great as this is. The winter temperatures (April to September) are remarkably uniform; there is no month of decidedly lowest temperature as in the Arctic At Framheim was recorded the lowest average yearly temperature heretofore found anywhere in the world, viz., 13.4 deg below zero Fahr Prof Meinardus advances a novel and interesting theory of the atmospheric circulation in the Antarctic Between latitude 60 and 70 a trough of low barometric pressure runs around the globe, south of this the pressure rises, forming the polar anticyclone. The strong easterly winds of the Antarctic coast he believes to be fed by air brought from lower latitudes by the cyclonic circulation This explains why they are not dry winds, as they would be if they came from the interior of the continent and belonged to the anticyclonic circulation Lastly, the polar anticyclone is a shallow one, and in the interior does not even extend as high as the land itself Above it lies a polar cyclone, which draws in air from the north This air comes from a vast oceanic region, and its moisture feeds the great continental glacier under which Antarctica lies buried, making good the loss due to evaporation and to the flow of glacier-ice into the sea

The 100-inch Telescope

THE vicissitudes attending the task of building a 100-inch reflector—by far the largest telescope in the world—for the Mount Wilson Solar Observatory have been watched with interest and anxiety by astronomers for nearly eight years At last the successful grinding of the great mirror is so far assured that active work has been begun on the construction of the mounting and dome. Foundations have been laid for the observatory building, and the telescope pier is about finished. The latter measures 20 by 45 feet at the ground-level and is 33 feet in height.

Driving Machine Tools With a Motorcycle

A MECHANICAL genius in Gettysburg, Pa., not only rides his motorcycle to and from work, but keeps it busy in his shop. He has rigged a device that makes it a portable power plant, operating his grinding machine. His specialty is sharpening lawn mowers, and he can double his day's output with less labor by this method. The engine is kept cool by fans, one on each side of the machine, which keep a stream of cold air blowing on it while running, and the machine often operates half a day at a time without overheating.

Motorcycle as a power plant in the amateur's shop. The engine is kept cool by means of fans.

Giant Penguins

THE accompanying photograph shows four giant penguins from the Antarctic (South Georgia). The two parent birds are white and dark brown. The young birds are covered with long gray-brown hair; it is, in fact, more like hair than like down or feathers. These penguins are also known as "royal" penguins, because of the appearance as of a regal mantle that fastens around the throat and hangs over the stumpy wings. The young have not yet grown such a mantle. These birds have just been presented to the Rotterdam Zoological Gardens, and every care will be taken to make them survive a Dutch summer. They walk upright and are very tame.

Four giant penguins from South Georgia which have been presented to the Rotterdam Zoological Gardens.

Water Power Pumping Plant of Paris

THE water wheel plant installed upon the Seine at Bougival and known as the "Marly machine" is one of the curiosities of the suburbs of Paris. Installed in 1858 in order to raise the water of the Seine up to Versailles for the use of the numerous fountains and basins of the chateau and also for the town water supply, the present plant has been in continual operation since that time, and is likely to hold out for many years to come. The first Marly machine was built in 1680. It used quite a number of water-wheels, together with such a pumping outfit as could be contrived at the time, and was, in fact, quite a success in such a primitive stage of the engineering art. But in course of time the plant finally wore out, and was first replaced by a small steam engine plant, which was scarcely able to elevate enough water for the city use, not to speak of the fountains, but at a later date it was decided to erect the present outfit under the direction of the eminent engineer, Dufrayer. The wheel house extends part way across the Seine, and the water flows underneath the building so as to drive the undershot wheels, these being five in number, 15 feet wide and 40 feet in diameter. They are each connected to four horizontal piston pumps, one of which can be seen in the foreground. The [illegible] capacity of the pumps is upwards of [illegible]000 cubic feet per 24 hours. Owing to the fact that the city uses part of the water, it was decided to discontinue the use of Seine water in 1898, and to obtain a purer supply from a number of large wells in the region of the Seine, so that the pumps now deliver pure water to the city, this being further passed through sand filters located near Versailles.

The forty-foot water-wheels of the "Marly machine," which pump the water for the fountains of Versailles.

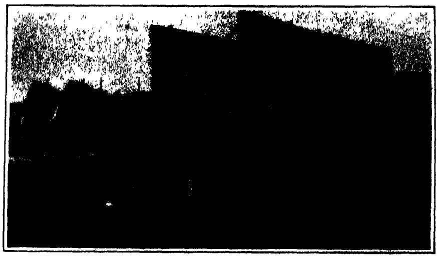
A Light Machine Gun

A NEW French machine gun has recently been adopted by the American army. This weapon is hardly larger than the rifle carried by the soldiers, and yet is capable of firing 200 to 500 steel bullets per minute. It takes two men to operate it. One man feeds the long strips of cartridges into the breech of the gun from the right, while the other man aims and keeps the stream of bullets pouring in the right direction. The gun weighs only 35 pounds, and, therefore, can be easily carried by one soldier. It dismounts in three pieces, which can be assembled again for action in 10 seconds. It works close to the ground, and the operators lie on the ground, which does not make prominent targets of them. No heavy tripod is necessary for its mount. The objectionable water jacket of other machine guns is eliminated and an air-cooled radiator takes its place, which saves about 25 pounds in weight. The cartridges used are in strips of 25 each, and are the same as used by the soldiers in their rifles. The bullet weighs one half ounce, and is of steel with a lead center.

Thirty-five-pound, air-cooled machine gun, capable of firing 200 to 500 shots per minute.

Folding Bandstand on Wheels

PROVIDENCE, R. I., hires bands to give free concerts once a week in each of the parks scattered about the crowded districts. But the city did not care to build bandstands at each park, since each is used very little. Accordingly, the Park Commissioners had a portable folding bandstand built for them. When the outfit was completed it weighed 3,400 pounds. The stand, when open, has floor space of 20 by 35 feet, and will hold thirty-five chairs. The rims of the wheels are very wide so as to protect the park grass. When opened, the sides are supported by upright pieces which extend sufficiently far above the stand for electric lights to be suspended from them.



Folding bandstand on wheels, which is hauled around to various parks where public concerts are given.

The United States Forest Service is using gasoline railway speeders for fire protection purposes. They follow up trains on steep grades where sparks thrown out by forced draft are likely to start fires.

Hands Misplaced in Egyptian Paintings and Sculptures

By James Arthur

DURING a journey up the Nile in 1908 I noticed, for the first time, a strange mixing of right and left hands in ancient Egyptian art, although I had been in Egypt before. So marked is this error that, I think, a count would show hands properly placed to be in the minority. In Fig. 1 we have Rameses I making an offering to the god Osiris, with two *right* hands, while the god's hands are correct, the "Key of life" in his right. In Fig. 2 Seti I is shown holding up his elaborate offering to the goddess Isis, with two left hands. The hands of the goddess are reversed. She holds the "Key of life" in the right hand at her left side! In these four we have all possible combinations: two rights, two lefts, right and left reversed, and right and left correct. When we consider that this went on for thousands of years it looks amazing. Surely the artists know what they were doing? Then how about the public? In trying to find some reason I noticed that the sculptor placed the thumb next the eye of the observer. This quite regardless of accuracy, it will not do to say "convention." We have plenty of conventions, especially in fashion plates, but we do not reverse things.

These photographs are from sculptures in the sixth Egyptian room of the Metropolitan Museum of Art, New York city. An Egyptologist writes me that he cannot find anything printed on this matter either before or since 1908, in which year I mailed postal cards from Egypt, showing the errors.

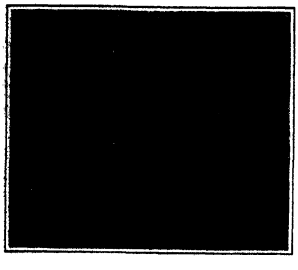


Fig. 1.—Rameses making an offering to the God Osiris, with two right hands, while the God's hands are correct.

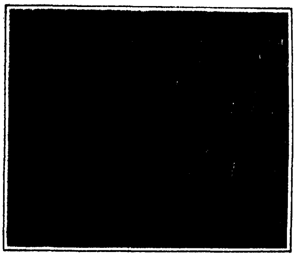

Fig. 2.—Seti I holding up an elaborate offering to the Goddess Isis, with two left hands. Hands of Goddess are reversed.

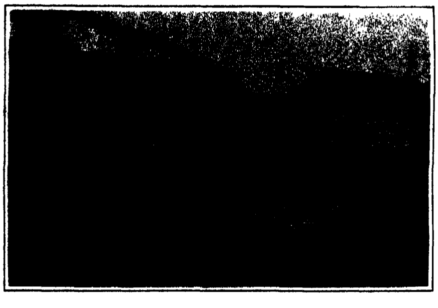
A Sectional Dumping Car

HERETOFORE most of the dumping of roadbed material for electric lines has been done by platform labor. A modern type of dump car has recently been developed that not only does away with the unsightly string of dump cars formerly used, but eliminates the danger of running such a train of cars through congested city districts, and at the same time reduces the cost of platform labor about 50 per cent. Through the suggestion of the Public Utilities Commission and the co-operation of an electric line and well-known car builders of Springfield, Mass., the electric dump car shown herewith has been developed. The new car has four compartments which take the place of three cars of the old type. The sections can be emptied separately, or at one time. When all are dumped it requires but one minute's time. The dumping is done by cables attached to the lower corners of each section, and which run over sheaves at locations 3-3 and 4-4. When fully loaded the new carrier conveys 24 cubic yards of crushed stone, each separate section having a capacity of 6 cubic yards. Weight of car with maximum load is 72 tons; without, 21 tons. The car is equipped with four 40 horse-power motors, and air brakes. It was built at a cost of about $6,000. In the cab of the car is a 10 horse-power motor for dumping the load.



Car that may be dumped a section at a time.

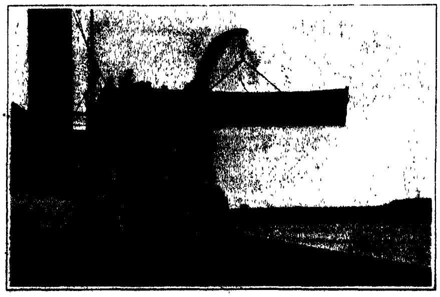
Single Boat Davit

ONE of the chief disadvantages of the common system of launching lifeboats lies in the use of two separate tackles which must be operated separately. During the panic of a shipwreck this is a source of serious confusion.

A new system of center slinging has been devised by Capt. Graham, a Glasgow shipmaster, which permits of using but a single davit, thereby greatly simplifying the launching operation. The accompanying photograph shows a davit of this type designed to handle a 28-foot lifeboat weighing 1¾ tons. The davit has a swivel bearing in the promenade deck and passes through a gland in the boat deck. The boat is hoisted by chain, which is doubled from the head of davit, led through a single sheave block, to which is attached a patent disengaging gear, which is absolutely *automatic* and cannot fail; for as soon as the boat is water borne the gear is bound to disengage.

Two men can launch the lifeboat in 50 seconds. The block can be recovered in 40 seconds ready for hooking on the second boat. On the "Titanic," the time occupied in rounding up and clearing manila tackle was 1 hour 15 minutes prior to hooking on the second boat, while the time taken on the "Olympic" at Southampton was 25 minutes, with 12 men operating. The lowering is under efficient automatic brake control, enabling one man to lower with speed and safety, on an even keel. The hook being positive in action releases the load automatically as soon as the boat is water borne. The chain travels over a sprocket wheel and stows in the hollow bottom of the davit. No handling is required, while fouling is entirely avoided. The davit may be readily modified to be operated by an electric motor.

The single davit has been subjected to most exhaustive tests by the British Board of Trade at various ports in Great Britain and has gained a certificate of approval for passenger vessels.



Launching a lifeboat with a single davit.

New Way of Treating Raw Silk

THERE is perhaps no industry in the country that has gone through so many stages of experimentation as that of silk dyeing, and it is by reason of this very fact that the silk industry has grown to such enormous proportions in the United States. A new process is now being used in the large silk-dyeing houses for the purpose of loosening the slender threads of raw silk that compose the skein, so that they will more readily "take" the dye. When the silk arrives at the dye house, after being packed in bales perhaps for months, the tiny threads are so closely pressed together that they must be separated as much as possible, and as this is not practicable by mechanical means, chemical processes must be resorted to.

Formerly this object was accomplished by using large boxes, about thirty feet long, three feet wide and three feet high. These boxes were filled with a weak solution of phosphate of soda, and the silk skeins were suspended on small wooden rods placed across the top and extending a few inches beyond the sides of the boxes. The silk was then moved back and forth in this bath by two operatives working together, one on each side of the box. At frequent intervals the silk was turned by the workmen so that all parts of it became immersed in the liquor. This process continued for about an hour, when the silk was taken out, washed and dried. The operation was repeated several times while the silk was passing through the various stages of preparation for dyeing, and it was slow and laborious work.

By the new process the phosphate of soda, of five degrees specific gravity, and heated to fifty deg. R. is placed in a series of rubber tanks, these tanks being connected with large hydro-extractors, each having a capacity of four hundred pounds of silk. Each one of the rubber tanks is supplied with a coil of lead pipe placed in the bottom through which a constant pressure of steam is forced for the purpose of heating the liquor to the required degree. The strength of the phosphate of soda solution also varies somewhat, according to the kind and quality of silk to be treated.

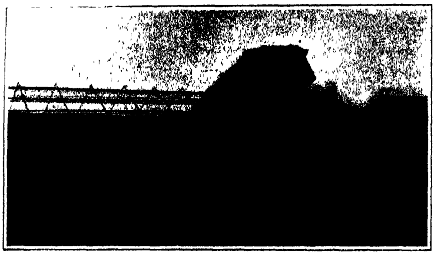
The silk is packed loosely in the hydro extractors, so that the phosphate of soda may thoroughly permeate every part of it and the machine is then slowly revolved while the phosphate of soda is pumped into it from the rubber tanks. As soon as they are filled the flow of soda is turned off and the hydro extractors continue to revolve slowly for about an hour. In this way every part of the four hundred pounds of silk which they contain is thoroughly permeated, and the fine threads of silk loosened in the skein and separated from each other, so that they can easily become saturated with the other chemicals and dyes used in the process of dyeing.

At the expiration of an hour the hydro-extractor is stopped and the phosphate of soda solution allowed to run back into the rubber tanks until the machine is empty. The hydro-extractor is then rapidly revolved or "whizzed" for ten or fifteen minutes until the silk is thoroughly dry. It is then taken out and a fresh supply of silk is put into the machine. The silk is washed on a washing machine, dried in a smaller hydro-extractor, and is then ready for the subsequent processes. By means of the new method of treating the silk the output of the dye houses is increased about one fourth and the cost of treating the silk materially reduced.

Sponges as a Fertilizer.—Mr. Joseph G. Smith of the United States Bureau of Soils has called attention to the present use and future possibilities of the loggerhead sponges of the Florida Keys as a fertilizer. They are said to grow in countless thousands in shallow water, where they are easy to gather, and citrus groves on the neighboring mainland have been fertilized with them with very satisfactory results.

The Motor-driven Commercial Vehicle

This department is devoted to the interests of present and prospective owners of motor trucks and delivery wagons. The Editor will endeavor to answer any questions relating to mechanical features, operation and management of commercial motor vehicles.



The dumping truck serves a variety of purposes.

Giving the cow a ride.

The Motor Truck on the Farm

By Ross Babcock, M.E.

TO the imaginative man, the place of the horse on the modern farm already has been taken by the massive motor truck and the scarcely less feebly kicking gasoline-motor-of-all-work. For though there is no new thought in the expression "the horse must go," the suggestion is there just the same—and it is a suggestion that is all the more potent because of the rapid strides that have been made by the farmer during the past year in adopting for his very own the type of horseless vehicle that was designed primarily for more densely populated trade centers, where the call of the crow and the smell of the soil never penetrate.

Part of the suggestion is conveyed by the very evident manner in which the present-day motor truck builder is endeavoring, either directly or indirectly, to cater to the needs of the farmer. He is endeavoring not so much to give the farmer what the manufacturer thinks he ought to have as to give him what he wants, *never once forgetting*, however, that minds trained to the ways of the draft animals may not be quite as quick as are other minds to grasp the significance of specially developed vehicles that not infrequently appear to the less sophisticated layman somewhat as round pegs in square holes

The manufacturer has shown by his attitude that he is willing and anxious to hold out a helping hand to the man behind the plow—to assist him to a better place in the world by solving at least a part of his transportation problems for him And *that the manufacturer really is sincere* in his manifestations scarcely permits of question, for he knows that as a general rule the farmer will be far more considerate of his power-driven equipment than will the average individual engaged in some other business, and that the ultimate benefit will be as much his own as it is the farmer's

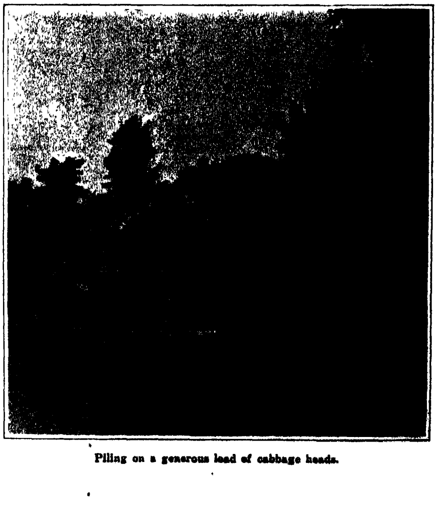
In many respects, the farmer whose acres lie within a radius of fifty miles or so of a big metropolis has a distinct advantage over his brothers whose farms are located less conveniently to the *ultimate market He can*, if he will, transport at least a part—probably the more perishable part—of his produce by motor truck more quickly than by railroad in a great many cases, and with greater certainty that it will reach its destination on time and in prime condition

As just one concrete example of the superiority of the motor truck over the horse-drawn vehicle, the case of one influential Long Island farmer may be cited With a five-ton truck, this man, whose farm is situated about thirty-five miles from the New York market, carries twice, and sometimes three times, as much produce to the city in one load as could be carried by one wagon and team, and he does it in a fraction of the time, and at a fraction of the cost of his horsed equipment.

For work of the kind, the heavier type *of vehicle of from three to five tons capacity* is the best, and in this connection it is interesting to note the tendency toward increased efficiency by reducing idle time to the minimum. The removable body has had an exemplary effect in promoting efficiency.

In operation, the removable body—*generally there are several of them where the* volume of the work warrants—is loaded while resting upon a "dead" wagon, which can be moved either by hand or by horses nearer to the work as the loading progresses. The truck chassis is in the mean time employed in doing other work, or, where several removable bodies are used, *in transporting* a load in one of them. "Dead" wagons are not necessary, of course, though they are a convenience. The removable bodies may be dismounted (by the power of the engine, be it added) upon suitable platforms conveniently located.

Hauling a heavy load up hill.



Piling on a generous load of cabbage heads.

How does all this affect the farmer? Let us suppose a hypothetical case which may not be so hypothetical after all. Farmer Smith is located, say, three or four miles from his nearest railroad shipping point. What will one three-ton chassis and three removable bodies do for him?

Assuming that one body is continually on the chassis *en route* to or from the station, which is the theory of motor trucking for real efficiency, the other two rest on easily erected loading platforms near to, or actually in, the field where the harvesting is being done. The truck returns from the railroad station minus its body, which is unloaded during the time the truck can return to the field, pick up another loaded body and make the trip to the station. Arrived, the unloaded body is substituted for the loaded one and the process repeated as many times as may be necessary.

By such means it is possible for the farmer to get all of his produce actually on the market days before "the other fellow," and, therefore, he is in a position to command better prices.

Needless to point out, a motor truck always can be used as a tractor and quite frequently it is possible to load the truck itself and then to hitch an ordinary produce wagon on behind for a trailer, in this way practically doubling the capacity of the truck.

Where the ordinary produce wagon is used for a trailer, however, a note of warning against excessive speed should be apparent, for obviously the wagon is not constructed for speed and cannot be expected to "stand up" under the strain of other than a moderate rate of progression.

As a means of carrying dairy products to a nearby market, there is much to be said in favor of the lighter power wagons. They are economical and comfortable, for as a rule, they are better sprung than are their horse-drawn predecessors—they must be better sprung to protect their mechanism—they are easily operated, and last, but not least, no weather holds terrors for them. They will fairly skim over ice and snow, and there is no necessity for curtailing speed. Similarly, they offer exceptional opportunities for providing protection for the operator, for though

LEGAL NOTICES

PATENTS

If you have an invention which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of more than sixty years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to PATENTS, TRADE MARKS, FOREIGN PATENTS, etc.

All patents secured through us are described without cost to the patentee in the SCIENTIFIC AMERICAN.

INQUIRY COLUMN

READ THIS COLUMN CAREFULLY. You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. *In every case it is necessary to give the number of the inquiry.* Where manufacturers do not respond promptly the inquiry *may* be repeated.

MUNN & CO., INC.

Inquiry No 9355. Wanted the name and address of the maker of triplex glass.

Inquiry No. 9356 Wanted the name and address of a manufacturer who can build an *automobile wheel*, also a *cigar vending machine*. Concerns in the middle West preferred.

Inquiry No. 9357. Wanted the name and address of a manufacturer of a machine for scalloped paper favors and cups.

Inquiry No. 9358.—Wanted the name and address of maker of a machine to cut all granulate leather

Inquiry No. 9359. Wanted the name and address of a firm that makes razor blades for all makes of safety razors.

Inquiry No. 9360 Wanted the name and address of parties making pipe fittings such as ferrules, stems and bowls such as could be used in the making up of calabash pipes for smoking

Inquiry No. 9361. Wanted to buy a Nut Cracking Machine, especially good for Pecans.

Inquiry No. 9362. Wanted the name and address of the makers of a machine for splicing ties.

Inquiry No. 9363. Wanted the names and addresses of manufacturers of machinery for printing on intaglio copper plates

Inquiry No. 9364. Wanted the name and address of buyer of mica in a crude state.

Inquiry No. 9365. Wanted the name and address of a manufacturer of machinery for embossing tin foil as is used in packing cigarettes.

Inquiry No. 9366. Wanted the name and address of a manufacturer of wire wheels, front axles complete with steering or separate, light sheet metal bodies, fuel tanks with cocks, pressed steel frames, mufflers, motors of the two cylinder opposed type, cushions and many smaller parts for cycle cars.

Inquiry No. 9367. Wanted the name and address of a manufacturer of an automatic centering machine.

Inquiry No. 9368. Wanted, the name and address of glass-bottle manufacturers or glass blowers who can manufacture a glass bottle and perforate it with some 12 small holes, in large quantities for export, to sell at a popular price.

Inquiry No. 9369. Wanted, the names and addresses of users of Indian Steatite (Soapstone), Corundum and other Indian minerals, in quantities.

Inquiry No. 9370. Wanted the names and addresses of manufacturers of small wooden articles, particularly in such soft woods as pine and fir, for articles such as toys, furniture, etc.

Inquiry No. 9371 Information wanted where one could buy or have made to order machine to be used for making solid back brushes.

Inquiry No. 9372. Wanted the name and address of [illegible] of a collapsible box about 15 inches [illegible] made to withstand [illegible]

the horse may be overloaded by such extra weight as is represented by a closed "cab" the power wagon carries it easily.

Buying the Truck on the Instalment Plan

By James McLean Helford

IN many instances, the intending purchaser of a motor truck is confronted with one or both of two difficulties—even after he has become convinced that a commerical vehicle installation will prove profitable in his business. He may be unable to supply the necessary capital to purchase an expensive truck outright; or he may have so large an investment in horse and wagon equipment that he could not easily convert their value into cash. In the latter instance, it would prove far more profitable for the owner to sell his horse and wagon equipment piecemeal and to invest immediately in one or more of the necessary trucks—as his business warrants.

But to such would-be purchasers of motor trucks, many manufacturers and dealers offer relief. While there may seem to be more or less odium and a sense of instability attached to the word "instalment," it represents a pure and simple business proposition, and is a plan whereby many a reputable merchant is enabled to continue with a profitable enterprise. Just as no large office building is erected for "cash" or is completed without the floatation of bonds or mortgages, so should it hardly be expected that every large business house would be willing to purchase its entire commercial vehicle equipment in a lump sum. But if a man desires to take advantage of any of the several instalment or "part payment" plans of selling motor trucks, he must first convince the manufacturer or dealer of his reliability and financial standing It is evident, therefore, that the credit department of the truck manufacturer takes an important position in regard to these time sales, and the business record of the intending purchaser is carefully investigated.

Further than this, the truck companies do not look with favor upon propositions in which it is found that the would-be purchaser is depending upon the truck itself to show a sufficient profit to meet the payments and interest when they become due. Improper handling, wrong routing, or many another condition can seriously affect the earning capacity of a motor truck, and therefore the intending purchaser must of necessity be able to show other sources of income before he can be considered a fit subject for the receipt of a car on the instalment basis. The purchase of a truck in such a manner, therefore, betokens strict business integrity, and far from being the rather questionable undertaking that many consider it, it becomes a high-class, legitimate proposition.

One large concern that has recently adopted the instalment system of selling trucks charges the full list price for vehicles so purchased. Twenty-five per cent of this list price is exacted to include the delivery of the truck, and the remainder is due within one year, in the form of twelve, equal, monthly payments. These payments are guaranteed by notes which bear six per cent interest and which, in some instances, must be indorsed by the dealer consummating the sale. In addition, the purchaser, upon delivery to him, must insure the truck for one year to cover fire, accident, and liability, and while such policies may be made out in the buyer's name, they must bear an indorsement in the form of a "rider," signing over to the manufacturers the amount of the policy, "as their interest may appear"—as it is stated in insurance parlance.

This provision regarding the insurance is made because the manufacturer holds title to the truck until the last of the notes, together with interest, has been paid. In order to establish this title, a lease or a chattel mortgage on the truck must be executed before the proper officer. Inasmuch as the law regarding the nature of such an obligation varies in different

FIRESTONE Tire Service Shops stand back of your delivery systems. They will help you keep your trucks in service at reduced expense. All large trucking centers offer Firestone service facilities, completely equipped to build entire new wheels if necessary.

If your trucks are not yet equipped with Firestone Quick Removable Rims of S. A. E. Standard, turn them in now to be standardized.

This will allow your own drivers to change a tire, even on heaviest trucks, in a few minutes with ease and sureness.

Firestone Tires, suited to your needs, on Firestone Rims, backed by Firestone Service Station help, insure lowest cost and highest efficiency. Write for truck equipment catalog or call for the Firestone man.

Starrett Combination Square—

Here's a tool that every mechanic and every man who works about his house should have.

It's a try-square with a *sliding* head which may be fastened at any point on the grooved scale which serves as the blade. In the head is a spirit level, and one face is at an angle of 45 degrees so that this tool may be used as a rule, square, level, bevel, depth gage, and marking gage. In addition it may be purchased with protractor head and center gage for fine work.

Ask your hardware dealer to show you this and other Starrett Tools. Send to us for our new free 320-page catalog No 20B, showing 2100 styles and sizes of tools with prices

Enjoy All the Pleasures of a Launch At a Fraction of the Expense

Time and again you've longed to own a launch—longed for some means of skimming about over river and lake without paying the penalty with a tired, aching back and blistered hands. Often you have wanted to go far across the lake or way down the river where fishing and hunting are best. But when you thought of the long, tiresome row, you became discouraged and denied yourself a world of fun and pleasure. Those days are past now. Your dreams and longings for a power driven boat—one that will quickly take you to the fishing or hunting grounds, the camp or summer home—can now be realized. And realized at an expense far below your fondest expectations. All you need is a common row boat and a

Caille Portable Boat Motor

—the handy little motor that attaches to the stern of any row boat by simply turning two thumb screws, immediately changing it into a reliable little launch. It develops 2 H P and steers with a rudder like a launch—not by the propeller Rudder is of our folding, stone-dodging type [Pat applied for] Weedless propeller is protected by a substantial fin Motor is adjustable to any angle or depth of stern Starts with half a turn of the fly wheel Weighs but 55 lbs Drives row boats 7 to 9 miles an hour or slow enough to troll Can be run in salt or fresh water Furnished with battery ignition or reversible magneto. Send for beautiful catalog

States, such papers must be passed upon by the purchaser's attorney, who must make a written statement to the effect that the lease or mortgage as executed is prepared according to the legal form exacted in the State in which the purchaser of the truck and the signer of the notes resides. He must also certify that such papers have been properly recorded in order fully to protect the manufacturer in the case of default on the part of the intending purchaser.

In order to make such an instalment system the more clear, let us consider the case of a light truck selling at an arbitrary figure—$1,350 say, to make the calculations "come out even." One fourth in some instances, and one third in others, is to be paid in cash. Assuming one third of the total to be required at the time of purchase, the cash due is $450, and the remaining $900 is to be paid in the form of ten or twelve monthly notes, with interest at 6 per cent.

In addition to the 6 per cent interest charged on the notes covering the unpaid balance on the truck, some concerns purposely charge on the basis of a greater total than that for which the truck could be purchased for cash. That is, for example, 6 per cent will be deducted from the list price that forms the instalment plan charge, if the truck is to be purchased for cash, and the buyer therefore saves, not only the interest on his notes, but also an additional 6 per cent on his investment.

The fact that many hard-headed business men have taken advantage of these instalment offers on the part of some of the motor truck manufacturers is evidence of the soundness of the business policies involved The motor truck business is still in its infancy, and it is but natural that such inducements should be made to prospective buyers as are offered to purchasers of articles that have been before the public for a much greater length of time. If the motor truck is indispensable, as it is surely proving itself to be, it should be made available for every small merchant and truckman who now uses but one or two horses and wagons, as well as for the large department store employing a fleet of a hundred commercial vehicles in its delivery system.

Motor Truck Notes and Queries

P. B. J. writes: "Why are the dual, or twin, tires used on large trucks? Would it not be cheaper to use one large tire on each rear wheel?"

A. The weight carried by each inch of tire width should not exceed a certain amount Therefore, when a heavy truck is loaded with several tons, the required width of tire becomes so great as to make a single tire exceedingly unwieldy. Furthermore, the cost of production of such a tire would be greater than that of two of one half the width It is also possible that one of the dual tires would wear more rapidly that its companion on the same wheel, and in this event, only the imperfect one need be replaced Another important consideration in favor of the use of dual tires on large trucks is the better facilities afforded for attaching the two separate tires to the rims of the wheel.

H. J. W. writes: "I understand that ten or twelve miles an hour is the speed limit recommended by tire and truck manufacturers for vehicles of three-ton capacity. I have heard the term 'high-speed trucks' used, however, and would like to know what is the speed and capacity of such, and what is their tire equipment."

A. Such vehicles are really more of the nature of delivery cars than trucks, for their total load seldom exceeds three quarters of a ton. A commercial vehicle of this type may be run at twenty miles an hour, or more, while many have speed capabilities of thirty and thirty-five. In the latter instance, pneumatic tires should as a rule be used, for their greater resiliency enables such speeds to be obtained without seriously affecting the motor, transmission, and other mechanical parts. Solid tires can be used on light trucks that do not exceed a speed of twenty

Where were you when the Chicago fire occurred?

Do you remember that great fire?

They said old Mrs. Leary's cow kicked the lamp over.

If results go for anything, that was the record kick for all time. For when that little blaze was stopped $290,000,000 worth of property had been wiped out.

Let's see, that was in 1871! The same year that Richmond Straight Cuts made their first appearance—and gained the reputation of being the best of all Virginia Cigarettes.

Many people have forgotten the Chicago fire. And that proves that we have a better memory for pleasures than for misfortunes.

Richmond Straight Cuts seem destined to go on forever. They have a quality men do not forget. They are still proclaimed the best of all Virginia Cigarettes.

Besides the regular package of 20, these cigarettes are also packed in attractive tin boxes, convenient for den, office or traveling, 50 for 40c; 100 for 75c. These larger packages will be sent prepaid on receipt of price, if your dealer cannot supply them

My friends tell me this is the most delightful smoke they know. One says, "I have never before found cigars mild enough, yet with the dainty flavor these have." Another says, "Just to my taste." Another, "If future orders are as good as the samples, I shall be perfectly satisfied."

This is my private Havana, selected after years of search for a perfect Havana leaf. The tobacco is secured for me by an expert in Cuba—from a mountain valley in the famous Vuelta Abajo district. Then it is made up and banded under my private monogram. I have never experienced so sweet, so mild a flavor—and I have smoked for 40 years.

See if they please you, too. Smoke five with me. Tastes in tobacco differ, but if you prefer a delicately flavored cigar, with a rare, mild aroma, you'll be captivated by this. I ship them by Parcel Post. You can order easily. The price is $5 per hundred—$2.60 for 50—all charges prepaid. I now buy this superlative tobacco in quantities that permit my making this low price. But even so, the number I can supply has its limits. Write me today.

Five Cigars Free

If you will send me 10 cents—towards forwarding expenses—I will mail you trial cigars. Smoke five with me—convince yourself. The price is $5 per hundred, $2.60 for 50—all charges prepaid. Use your letter-head, please—stating your position—or your business card, and write now for these cigars.

miles an hour, but as a rule, pneumatics are the more popular equipment. A seemingly satisfactory compromise has been reached by at least one maker of a light truck, who employs solid tires at the rear wheels, where the wear caused by the tractive effort is greater, and pneumatics in front, where the weight distribution is less, and where the motor may be partially insulated from many of the excessive shocks of high-speed travel.

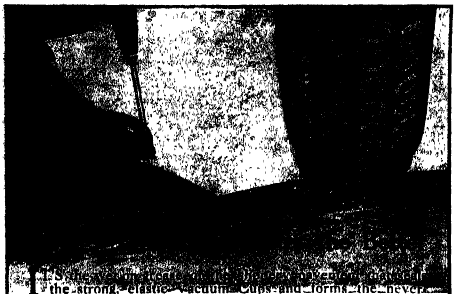
M. A. L. writes: "One of the cylinders of the motor in my three-ton truck has suddenly lost its compression-retaining ability, and, therefore, does not deliver its full share of the power. The garage man tells me that the rings have probably worked around so that the opening of each is opposite that of its neighbor. Please tell me how this may be accounted for and how a repetition may be prevented."

A. We assume that there are three rings on the piston in question. When the motor is assembled, the opening of each ring should be opposite the "back" of the one adjacent to it. That is, if the first ring is set with its opening toward the front of the motor, the second should be placed so that its opening faces the rear of the motor; the third ring, in turn, will then face forward. The rings should be held in these relative positions by notches in the edge of their open ends that fit into pins set into the proper places in the ring grooves of the piston Insamuch as the openings of the first and third rings are in a line with each other, it is only necessary that the middle ring be moved out of place half a turn, or 180 degrees, before a free path for the escape of the gas in the cylinder will be furnished To be sure, it is seldom that the ring can "ride" up on its pin, and yet through a faulty installation, several instances of this have been known to occur. The remedy lies in reinstalling the ring in its proper position, or in the use of a type of ring that has no free opening for the escape of the compressed gas. This latter type is really two rings in one. These are mounted concentrically, with the flanged edge of one overlapping that of the other so that both the outside and inside present a smooth surface. Each of these two rings has its own notched opening, but as this rests firmly against either the inside or outside surface of its companion ring, the device is elastic and flexible without affording a single break in the contour of the ring as a whole

P. W. H. writes: "My truck is equipped with single, four-inch solid tires. As the frame and motor seem to be easily capable of carrying nearly double the rated load, and as I understand that overload injures the tires more than any other part of the truck, could I increase the carrying capacity of the truck one hundred per cent by replacing my rear wheels with those having dual rims on which twin four-inch tires would be used?"

A. While it is true, as you say, that the tires are the principal sufferers from overloading, nevertheless, the motor and transmission may be harmed by such a practice, and we would strongly urge you to keep the average loads of your truck well within the limits set by the manufacturer Furthermore, it is not considered that two tires of a given size will carry double the load for which a single tire of the same size is suited For example, if a four-inch tire can support a thousand-pound load without difficulty, it is assumed by conservative manufacturers that four-inch dual tires will carry fifteen hundred pounds with the same margin of wear. This allowance is made to provide for the times when one or the other of the dual tires will carry the entire load of that wheel, as, for instance, when the truck passes over a stone or a rut that comes in contact only with one of the dual tires.

The Crozet Islands, in the southern Indian Ocean, have been annexed by France. They are uninhabited and are rarely visited, though they lie near the route between Cape Town and Melbourne. The "Gauss" Antarctic expedition paid a visit to the islands in 1901.



IT'S the [illegible] the strong, elastic Vacuum Cups and forms the never-slipping suction grip.

IT means bigger, better, cleaner business. It is the inspiring insignia of 140 clubs, with a membership of over 10,000 earnest men. Learn what the Associated Advertising Clubs of America are doing for honesty in business; for more systematic, scientific and successful methods of distribution, advertising and salesmanship. Attend the Tenth Annual Convention of the A. A. C. of A.

TORONTO
JUNE 21-25, 1914

Interesting Program

The program for this great convention is comprehensive and diversified, covering every phase of modern merchandising. The sessions will be addressed by able, successful men, open meetings, devoted to a wide range of special topics, will give everybody a chance to ask questions and hear his own problems discussed by the men who have met and solved them.

Edward Mott Woolley

the famous writer on business topics, has made a study of the A A. C. of A and their work, as well as of the plans for the Toronto Convention. He has embodied the result in a little book, "The Story of Toronto". This book paints a graphic, inspiring picture of what this great movement signifies.

It will be sent free to all business men asking for it on their business stationery—together with detailed facts as to the convention program and rates for accommodations

New Publications of Harper & Brothers

Harper's Gasoline Engine Book

By Alpheus Hyatt Verrill

This new addition to Harper's "Tell-Me-How" series will serve as a simple and practical guide for all those who own, use, or operate gas and gasoline motors. While intended for boys, it will prove of equal value to older readers, as it is more exhaustive than any book on the subject hitherto published—with the exception of strictly technical works. Clear and simple diagrams and illustrations enhance the value of the book.

Illustrated. $1.00 net.

Harper's Book for Young Gardeners

How to Make the Best Use of a Little Land

By Alpheus Hyatt Verrill

This book has been prepared to show how much profit and pleasure may be obtained from simple gardens, and how to plan, arrange, and care for them properly. Mere theories and elaborate methods have been avoided, practicability being the purpose of the volume It tells what soils are best adapted to certain plants and shows how remunerative kitchen gardens may be made. School gardening, experimental gardening, ornamental gardening are all explained, and the author shows what can be accomplished at a small outlay in a city back yard or vacant lot

Fully illustrated. $1 50 net.

Planning and Furnishing the Home

By Mary J. Quinn,

Instructor in Design, School of House Science and Art, Pratt Institute

The place in which you live, house, apartment or room, is treated in a practical way.

Miss Quinn goes into the question of good furnishing at a cost which is possible and practical for the average homemaker. This book is intended for the everyday homemaker who wants her home to be beautiful, but does not know how to go to work to bring about the result.

RECENTLY PATENTED INVENTIONS

These columns are open to all patentees The notices are inserted by special arrangement with the inventors Terms on application to the Advertising Department of the Scientific American

Pertaining to Apparel.

ADJUSTABLE SHOE BUCKLE FASTENER.—C. M Bonham, 2184 Seventh Ave., Manhattan, N. Y, N. Y This invention relates to shoe buckles or ornaments adapted to be used particularly in connection with pumps, although it is not limited exclusively to this application, and the invention has to do more especially with fastening or attaching devices for buckles or other ornaments.

STORM SLEEVE—H. Hertz, 115 E. 96th St., New York, N. Y. This invention provides a garment having sleeves for coats adapted particularly for chauffeurs or other drivers, and having the appearance of ordinary sleeves provided with outer cuffs, but in another adaptation providing effective hand coverings, keeping out wind, snow, or rain, the arrangement being such in the latter adaptation as to completely exclude the elements.

Of General Interest.

COMBINED CHAIR AND BASKET—B. H. Goldstein, care of J. Cohnen & Bros, 223 Cherry St., N Y, N. Y. This invention relates to improvements in combined chairs and baskets, and has for an object the provision of an improved structure which will afford a seat for an operator and a suitable convenient receptacle for the operator's work.

MONOCLE AND THE LIKE—H. T. Louch, 65 Hatton Garden, London, E. C England. This invention relates to monocles, magnifying lenses and the like, which are usually held in position by contraction of the muscles in the neighborhood of the eyes, the object of the inventor being to devise such improvements as will enable the articles to be held in position while at the same time conducing to the comfort of the wearer without impairing the efficiency of the device, or rendering it unsightly

STILL.—C L. Turner, 180 Madison Ave, Tompkinsville, N Y. This invention provides a still wherein fractional and continuous distillation may be performed, provides a still for the production of fractional distillation of hydro-carbon oils or other volatile liquids, provides means for conserving the heat employed in the distillations; and provides means for increasing the output of stills adapted for practical distillation

Hardware and Tools.

KEY RING LOCK—D C. En Earl, Hotel Colorado, 1634 Larimer St., Denver, Colo The purpose here is to provide a lock which is in the nature of a puzzle that may be readily operated by one who understands the construction and purpose of the lock, but which is exceedingly difficult to open by one who does not understand the operation

VALVE GRINDING TOOL—H. R. Parsons, Sharpsville, Pa The invention pertains to valve grinding tools utilized to grind in valves on automobile motors and other mechanisms where valves are used, the object being to provide a tool having means to engage a valve, and also provided with means whereby the operator may readily and conveniently press downwardly upon the same and rotate it at the same time, utilizing both hands in part performance of each operation

DEVICE FOR OPENING ELLIPTICAL SPRINGS.—C N Sowden Guantanamo, Cuba This invention relates to a device to be applied to laminated or leaf springs, such as elliptical or semi elliptical springs, and more particularly refers to that form of device for the indicated purpose, in which opposed wedge members have relative movement toward and from each other, to be entered between the leaves of the spring and withdrawn therefrom

Heating and Lighting.

SAFETY VALVE—H Steinberg, Huntingdon, Pa. This inventor provides a safety valve for attachment to a hot water boiler, especially those connected with stoves and ranges, which will serve the purpose of permitting the escape of excessive steam pressure when the water reaches a boiling point, thus obviating explosions which commonly occur.

Household Utilities.

FOLDABLE GAS STOVE.—R S Way, 415 No Grand, Los Angeles, Cal This stove is adapted to be folded into a casing set in a recess in a wall, to take up little room and not detract from the appearance of the apartment, to allow of easily unfolding the stove for use, and to automatically shut off the gas supply when folding it into the casing or to turn on the gas supply when moving the stove into extended position.

SANITARY GARBAGE RECEPTACLE—S I Segall, 2018 83rd St, Brooklyn, N Y This invention has reference to storage receptacles designed to store garbage, trash and the like, and has for an object to provide an improved structure which will automatically close itself after each time the same is opened

CURTAIN CLASP.—W H. Wallin, Box 5, R F D No 2, Stromsburg, Neb This improvement relates to devices for clasping a curtain on a curtain pole to prevent the curtain from bunching and to maintain it properly draped It provides a clasp having effective gripping engagement with a curtain, and one capable of a great variety of ornamental effects.

Machines and Mechanical Devices.

APPARATUS FOR TAKING OR REPRODUCING ANIMATED PICTURES.—L. H. Hurt, 114 Rue du Temple, Paris, France. The present invention has for its object a special operating device obviating numerous disadvantages. By reason of its special combination, this device puts kinematography within reach of the public and enables photograph amateurs to take successively several animated scenes without being compelled to go in a dark room for substituting a plate for another one in the photographic apparatus.

TANK SIPHON.—P. Balze, 200 Christie St., Leonia, N. J. This invention relates to water distribution, and has particular reference to siphons for periodically delivering fluids, especially water, from tanks Among the objects is to provide a siphon adapted especially for flush tanks, the nature of the siphon being such that it is valveless and hence precludes any possibility of leakage.

PROJECTING APPARATUS FOR MOVING PICTURE MACHINES.—G. E. Ripley and W. N Gladson, Fayetteville, Ark., and R. E. Thompson, Heber, Ark. Address the second, care of University of Arkansas, Fayetteville, Ark. The invention is an improvement in projecting apparatus for moving picture machines, and has in view a reflecting mechanism to cause the image of one picture to dissolve into the next without employing a tinted or softening light, or otherwise lessening the brilliancy of the screen during the picture change.

MACHINE FOR CUTTING BREAD.—E. Schmidt, Geb. Walter, Berlin-Tegel, Germany. This invention relates to a machine for cutting bread It is provided with a knife adapted to operate like a lever, the loaf of bread to be cut being placed on a grid consisting of rods, which, when the machine is in use, are at right angles to the knife The ends of the rods are secured to standards, to one of which the knife is pivoted

Railways and Their Accessories.

CAR FENDER—J. P Geraghty, 50 Hamilton Place, Jersey City, and G. W. Naylor, Jersey City, N. J. The invention provides a fender more especially for use on surface cars and arranged to normally hold the apron frame a distance above the track to clear switches, paving stones, etc, to cause the apron frame to move in an inclined position on a person or other object falling onto the track, and being struck by the gate, and to immediately cause the apron frame to swing back into normal position as soon as the person or object passes onto the apron frame, thus preventing person or object from being run over or injured by preventing a hand or foot from passing under the apron frame.

Pertaining to Vehicles.

SIGNALING APPARATUS—E. D. Lopez, New Orleans, La., care of Elite Letter Co., 41 W 33rd St, New York, N. Y. This device is for use on automobiles and other moving vehicles, and the object of the invention is to enable the driver to give notice to the car behind whenever he intends to stop or turn, without necessitating the removal of the driver's hands from the brakes or steering gear when the operation of stopping or turning is to be effected.

ACTUATING MEANS FOR SWIVEL LAMP HOLDERS—C. N. Sowden, Guantanamo, Cuba. This invention relates to lamp holders for automobiles, locomotives, and other vehicles having means for automatically turning the holder in the direction in which the vehicle is turned, and manually controlled actuating means. It refers more particularly to lamp holders and their appurtenances of the character forming the subject of the application filed by Mr. Sowden, Serial No. 728,970

AUTOMOBILE FENDER.—J. B. Foret, 633 Biddle Ave., Ford City, Mich. By means of this device a person who happens to be in front of an automobile may be prevented from suffering injury by the vehicle The fender has a grab rail, which may be seized and which tends to cause the lifting of the outer portion of the fender, thereby removing the person's clothing from the ground and preventing it being caught between the fender and the ground.

Note—Copies of any of these patents will be furnished by the Scientific American for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

We wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject matter involved, or of the specialized, technical, or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade mark applications filed in all countries foreign to the United States.

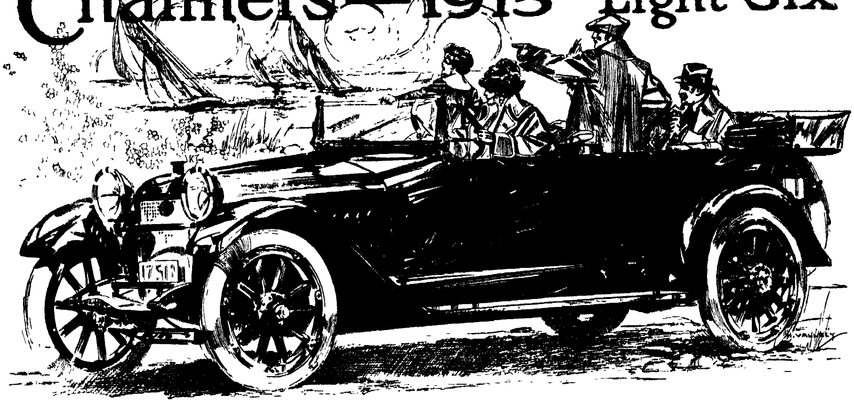
Chalmers—1915 "Light Six"



A New "Light Six" of Chalmers Quality—$1800

In addition to the famous Master "Six" at $2175 we now offer you the Master "Light Six"—a new Chalmers model at $1800.

Here is a 1915 car at $1800 with all the features that have given "Sixes" first place in the high priced field: Silence, smoothness, flexibility, beauty. It has, besides, what "Sixes" in the past have lacked: A low first cost, which makes it easy to buy; low operative cost, which makes it easy to keep.

The Master "Light Six" is a full year ahead; in style, in mechanical design, in simplicity, in efficiency. That's why thousands who once thought a "Six" an extravagance are now ordering 1915 Master "Light Sixes" faster than we can build them.

A "Six" or Nothing

This is the car for which thousands who would have a "Six" or nothing have waited.

The 1915 Master "Light Six" offers for the first time the full measure of 6-cylinder silence, smoothness and flexibility at the price of any comparable "four."

The Master "Light Six" at $1800 makes it unnecessary now to pay a high price, or a high maintenance cost to get six-cylinder luxury.

This 1915 Chalmers answers the last arguments of the four-cylinder builders —those of price and economy.

A Lighter Master "Six"

What the Chalmers Master "Six" at $2175 is among high powered cars, the 1915 "Light Six" at $1800 is among cars of its class. It has the same Master Motor, though built on a lighter scale. It has small bore and long stroke to give it flexibility; perfect balance to give it smoothness; right design to give it silence.

Its Chalmers-Entz electric starter makes the motor non-stallable. Tapered bonnet, oval fenders and streamline body rank it with the expensive foreign cars in looks.

Its lighter weight means an added economy. Yet it is heavy enough to make it safe in any emergency, comfortable on any road. Don't make the mistake of buying too light a car. The difference in gasoline consumption between a medium weight car and a flimsy car won't amount to $25 in 10,000 miles, and $25 won't buy many repairs for a car so light that it shakes to pieces in ordinary service.

Like all Chalmers cars, the 1915 "Light Six" is built to give satisfactory service through many seasons.

Buy This Car for Economy's Sake

Men want silence for its charm, smoothness, for its comfort, and flexibility for its convenience And they want these six-cylinder qualities, too, because they make motoring nerve soothing, not irritating You can drive a Chalmers "Six" 200 miles and be less fatigued than after 100 miles in a "four." Forty miles an hour in a "Six" doesn't give the nerve rasp of 25 miles in a constantly vibrating "four"

Men want these qualities for economy also. They know that vibration means needless strain on gears and bearings as well as nerves; power wasted in joggling the car instead of driving it.

They know that absence of noise means absence of undue friction; that a flexible motor means an economical motor. They know that only a "Six" can have these qualities So they buy the 1915 Master "Light Six," for its economy as well as for its charm.

A Car of Super-Value

It is hard to believe that any car at $1800 could possess all the advantages we claim for the Master "Light Six." Until you see it, you cannot realize its distinguished beauty; until you ride in it, you can know nothing of the extraordinary value it offers at the price.

When we say the 1915 "Light Six" is a year ahead of others, we mean just what we say

In design, in luxury, in endurance, in good looks we believe this to be the most advanced "Six" on the market. It has today the features of construction and equipment which most cars in the $2000 class will not have for another year

So we urge you to take the Chalmers Test Ride with our nearest dealer. Let the car itself prove its super-value.

Try to Match It

After you have taken the Chalmers Test Ride, challenge any comparable car to duplicate the performance Compare these features item for item with any car at near the price. We'll leave the result to you

Six Cylinders
30 to 50 Horsepower
126-Inch Wheel Base
Electric Starter
Non-Stallable Motor
Electric Lights
Tungsten Steel Valves
Streamline Body
Molded Oval Fenders
Triple Heated Fuel
Timken Bearings
Interlocking Gears
Chalmers Sectional Piston Rings
Cork Insert Disc Clutch
Clean Running Boards
Left Drive
Center Control
Rayfield Carburetor
Tapered Bonnet
Underslung Springs
Full Equipment

The Larger Master "Six"

2, 4 or 5 passenger type, $2175
6 passenger Touring Car, $2275

For the man who wants a larger and a higher powered car, there's our Master "Six", the fastest selling "Six" at its price in the country

This Master Car set a new standard among the larger "Sixes" for silence, smoothness and flexibility, its modest price and low upkeep set a new mark for economy among cars of maximum luxury

No matter how high your ideals of superlative merit in a motor car the larger Chalmers "Six" will satisfy your most exacting requirements.

Former owners of $4000 to $5000 cars are fast finding out that in the Master "Six" they secure the same six-cylinder value without the usual expense of a car of high power and large size. They say that a really better car no one can buy; a costlier car no one really needs.

Please send me literature on the 1915 "Light Six" and the larger Master "Six"

Electrically Driven Machinery and Westinghouse Electric Experience

THE leading plants in over one hundred industries in this country are manufacturing all their goods with electrically driven machines.

They have experienced a reduction in manufacturing costs, obtaining at the same time a higher quality of product.

Even established factories that have found it necessary to scrap old fashioned machinery in order to install electric drive have saved such expense in a very short period.

The example of these leading factories is being followed by others. But in order to save a few dollars on the first cost the temptation is to apply motors of untried qualities, and to apply them without regard to the operating characteristics of the driven machine. The wise manufacturer will not make this mistake. He will invest in motors that have a name and that are exactly suited to his conditions.

Here are the questions which must be answered: "Who makes these motors? What *experience* has this maker had in applying motors to my business? What is the general reputation of this maker for giving service *with* his product?"

Westinghouse Electric *experience* in applying motors industrially places this Company in an unusual position in relation to every such prospective application. It covers every industry to which motors have been applied. The Company's written data on these industries is probably the most complete information ever collected on this special subject.

There is no experimentation at the customer's expense in the case of Westinghouse installations. There is always an intelligent understanding of the peculiar conditions and needs of the customer's business.

So far as design and years of service are concerned, the factory that buys a Westinghouse installation buys the *Westinghouse name*—a name which has been associated with important electrical developments ever since the Westinghouse Electric development of the alternating current.

It buys an organization which covers the country with offices and service stations. In short, it adds to your factory a complete engineering organization, one with a world-wide reputation.

The cost of such service as the Westinghouse organization offers is no more than the cost of the very best machinery possible to build would naturally be. It is certain that the negligible upkeep expense makes a Westinghouse installation the very cheapest in the end.

Any manufacturer interested will do well to dictate a line to us. Or any employee with the interest of his firm in mind may have certain special literature bearing on electrical drive for his particular industry. Address Dept. MJ.

The Problem of the Hudson River

How the Model Experimental Basin and the Moving Picture Machine Solved It

By Robert G. Skerrett

THE United States model experimental basin at Washington has recently performed a new service; it has helped the Government authorities to solve some of the vexed questions relating to the matter of pier extensions into the Hudson River. This it has done by reproducing in miniature the physical peculiarities of the dock encroachments and the tidal prisms of the North River, more especially at that section between Castle Point on the New Jersey shore and the Chelsea section of the New York city piers.

The army engineers and the experts of the Dock Department of the metropolis could not agree on the probable effects of further extensions to the Chelsea piers. The army engineers believed that further encroachments upon the flow of the river would cause serious perturbations and probably increase the velocity of the tidal movements. The city authorities wanted to build longer piers within the narrowed section of the river in order to accommodate 1,000-foot liners. The river was already but 2,800 feet wide navigably.

It was, therefore, urged that tests be made at the tank in Washington, and Naval Constructor D. W. Taylor and Col. H. C. Newcomer set about devising facilities and planning suitable models for this exceptional undertaking.

The army engineers had more than an inkling of the need of just such an investigation, for the history of the river during a number of decades told a convincing story of what the building of piers, the reclaiming of considerable areas of land along the shores, and the increased traffic had wrought in the interval. From 1858 to 1912 the velocity of the ebb tide had increased 60 per cent at that section just north of the Chelsea region, while immediately south the corresponding normal outgoing tide had gained in rapidity a matter of 87 per cent! As the "bottle-neck" lying between the Chelsea piers on one side and Castle Point on the other had narrowed the while, this means an ebb velocity of quite 4.08 miles an hour.

These changes have imposed a heavy tax upon river traffic, and especially upon tugs with tows and, prospectively, upon self-propelled canal boats—the speed of the latter within the canals being limited to four knots an hour. Hence, these boats would have to add greatly to their engine power for the single purpose of navigating a very small section of the river when trying to work up stream against the ebb. This was not all. These changes in the speed of the tide had well-nigh put a stop to all heavy towing in that part of the river during the periods of greatest current velocities In short, the bulk of the lightering and barge work had to halt until the sweep of the tide slackened. A heavy handicap upon harbor traffic was imposed.

Because of the dangerous and disastrous forces exerted by suction between ships within "constricted waterways," Col. William T. Rossell, as senior member of the Harbor Line Board, urged that experiments be made in the naval tank at Washington not only to discover the possible effects of further narrowing of the river by pier extensions, but to study the perturbations set up in the water by the movements of incoming and outward bound liners when passing other craft or when flanking the open ends of docking spaces where other vessels were lying. Col. Rossell believed that these great express steamers seriously disturbed the river's normal sweep for considerable distances on either beam, and that these forces might constitute a serious menace to river traffic and to the vessels tied to the piers

The basin at Washington was provided with a false bottom resting upon heavy steel I-beams, and the simulation of the width and depth of the river was upon a scale of 15/1,000. This false bottom was painted a solid color and then marked conspicuously by cross-lines which cut the reflecting surface into numerous squares Attached to the underside of the towing carriage was a large mirror, at an angle of 45 degrees to the water, which reflected the false bottom, and made it possible for a moving picture camera located 75 feet in advance to take photograph of the changing view. Anchored over this false bottom were small aluminium buoys, to which were attached vertical rods the positions of the tips of these rods at or below the surface being nicely controlled. The tips of these rods represented, for the time being, imaginary particles of water, and the aim was to trace the beginning, the directions, and the amplitude of their movements when disturbed by the subsurface perturbations set up by the approaching, passing, and retreating model as it was towed by the carriage. At the same time, a large dial on the carriage indicated the position of the model on its course, the face of the dial being divided into elements of the length of the miniature channelway

Two models were provided for the experiments, one 15 feet long, representing a 1,000-foot liner, and the other 10 feet long, standing for a ship of the same shape, but only 666.6 feet over all The larger model was equipped with twin screws driven by an electric motor within the craft, and when running in this fashion the mission of the carriage was merely to guide its course. The object of this novel departure in tank experiments was to determine whether or not the action of the screws added materially to the force and zone of the water disturbances The smaller model was placed alongside the piers to test the effects of the passing of the miniature 1,000-foot liner, and above the 10-foot model was suspended a screen by means of the cross-lines of which the camera could record the resulting movements The 15-foot model was towed or run at four different speeds to represent a 1,000 foot liner moving at the rates of 6, 10, 15, and 20 knots an hour The equivalent actual speeds on the part of the model were respectively, 0.735, 1.23, 1.84, and 2.45 knots It was found that there was remarkably little difference in disturbance when the model was towed or when

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement

Once More the Anti-vivisectionists

A VERY ingenious German once wrote a bitter book called "A History of Human Stupidity." In it he chronicles many delectable examples of medieval superstition, which retarded the progress of the world by centuries, as well as numerous examples of modern asininity. He holds up to ridicule not only the foolish way in which science was retarded by religious persecution in the middle ages, but also such supremely foolish acts as that of a European peasant who buried himself alive in order to escape the census-taker.

Some day that "History of Stupidity" will be amplified. Its most distressing new chapter will be devoted to the anti-vivisection mania which threatens to strangle scientific research, of whose inestimable benefit to humanity there cannot be the slightest question. In this campaign which ignorance, fanaticism and sentimentality have waged against humanity, surely the pinnacle of absurdity was reached when the bill to permit the Rockefeller Institute to establish a research laboratory in the State of New Jersey for the study of animal diseases and their cure was vetoed by Governor Fielder. One million dollars have been contributed by Mr. Rockefeller for research work on animal disease—research which is surely of vast importance when it is considered that our annual loss through the sickness of domestic animals amounts to one hundred million dollars for cattle alone and about seventy-five million dollars each for hogs and sheep.

Any one who has followed the proceedings of the recent medical congress in New York, an occasion upon which the most distinguished surgeons and physicians published to the world the progress which has been made in recent times in alleviating human suffering, must have been impressed with the high ideals of those who experiment upon animals in order to discover new methods of curing disease. If we are to credit the anti-vivisection ravings it might be supposed that the members of the Rockefeller Institute and similar institutions have no other object in mind than to obtain some devilish enjoyment by torturing guinea pigs, rats, and dogs. Of the great personal risks that these men run in handling deadly bacteria, of the weeks and weeks of patient experimenting, of the tragedies and martyrdoms of medical science, one hears nothing.

A score of medical men who could ill be spared have perished as a result of their special work in the field of X-rays. In his sixty-fifth year Dr. Robert Koch, the father of preventive medicine, remained for eighteen months on one of the Sese Islands in Victoria Nyanza, fighting incessantly with mosquitoes and ants and enduring "impossible food." With only one white companion, an army surgeon, he braved fevers and epidemics until at last he discovered crocodile's blood to be the chief nourishment of the tsetse fly, the voracious insect which transfers the trypanosomes, the specific cause of the sleeping sickness. Anti-vivisectionists would do well to read that wonderful letter which Koch wrote to his friend, Dr. Libbert, in which he says: "The flies engage our attention less than their victims. What a wonderful privilege it is to be able to save human beings who are doomed to certain death! It is this that makes it a real joy to be a physician."

What have anti-vivisectionists to say of the labors of Shiga, Ross, and Manson, men who have worked in daily contact with the deadliest toxins, all for the purpose of making the tropics and above all infection-ridden India tenantable by white men. And what shall be said of that committee of medical men which in 1900, in order to investigate the theory of Dr. Finlay that it was a mosquito which conveyed to human beings the germ of yellow fever, cheerfully volunteered to run the risk of subjecting themselves to the bite of the yellow fever mosquito? Surely war can display no finer heroism than this, and surely men who can make such great sacrifices can not be guilty of wanton cruelty to the lower animals.

Economy of the Modern Steam Engine

THE economies which have been secured in steam engine practice by the introduction of the steam turbine are strikingly illustrated in the installation which is being emplaced at the power station of the Interborough Rapid Transit Company, East River and Seventy-fourth Street, New York city, where the three largest turbines in the world are being built by the Westinghouse Company for the operation of the new subway. The turbines will supply sufficient electric current to operate 135 fully loaded ten-car trains accommodating 135,000 people. They are of the cross compound type, and consist of two sections, a high pressure and a low pressure unit. The high pressure unit will receive steam at 200 pounds pressure, and will drive a direct-connected generator running at 1,600 revolutions. The exhaust from the first unit will be utilized by a larger, low pressure unit, running at 750 revolutions per minute. From this the steam will pass to the condenser. Each turbine will be direct connected to a dynamo which will deliver 30,000 kilowatts, or about 41,000 horse-power; and, at full overload, each machine can deliver 36,000 kilowatts, or practically 50,000 horse-power, for a short period of time.

The economies of the turbines, as compared with the existing reciprocating engines, are many and very large. The turbines occupy less space, weigh less, effect a large saving in lubricating oil, and call for a smaller operating staff. Thus the new turbines will require about 1,645 square feet of floor space, representing an area measuring 31½ feet by 52 feet, and this is about the same as that occupied by the original reciprocating engines installed in 1901, which were illustrated at the time in the SCIENTIFIC AMERICAN. But although the space occupied is the same, the total output of power will be four times as great as that from the old plant.

The amount of steam used, and the enormous amount of cooling water required for the condensers, afford figures that are positively astonishing to the layman. Each unit will use about 350,000 pounds of steam per hour, and to condense this steam so that all the benefits of a vacuum may be obtained in connection with the low pressure unit, each turbine must be provided with a condenser containing 50,000 square feet of cooling surface. To insure this the condenser will contain 36 miles of brass tubing one inch in diameter. The necessary amount of cold water for circulation through the tubes will be drawn from the East River, and through each condenser there will be passed every hour 4,500,000 gallons of water. To pump this amount of water through the condensers for the eight units which will be ultimately installed calls for a tunnel 12 feet 4 inches wide and 12 feet 4 inches in height.

The saving in the coal bill by the use of turbines is truly remarkable. In the old cross compound reciprocating engine only 17½ per cent of the heat evolved by the combustion of the coal was turned to practical use, or as the engineers say, the thermal efficiency was only 17½ per cent. Moreover, 17 pounds of steam had to be consumed to deliver one kilowatt of power for one hour. With the new cross compound turbines a kilowatt of power will be secured on a consumption of 11¼ pounds of steam per hour. Under the present operating conditions 300,000,000 gallons of water are turned into steam every year for the use of the reciprocating engines. The new turbines will do the same work on 200,000,000 gallons of water with a corresponding reduction in the amount of coal that must be burned on the grates of the boilers.

The Mexican Navy

MEXICO is not entirely devoid of a navy. In fact, she possesses seven fighting ships, possibly four or five transports, and, for harbor service, she has three old schooners built by that Laird firm which was responsible for the armed cruisers which gave the North so much trouble during our civil war. The largest vessels of her little fleet are two cruiser transports, the "General Guerrero" and the "Progresso." These are modern ships, the first built by Vickers, Maxim, in 1908, and the second by Odero, in 1907. The "General Guerrero" is a vessel of 1,880 tons, armed with six 4-inch guns and two 3-pounders. Her engines of 1,200 horse-power give the ship a speed of 12 knots. The "Progresso," of 1,600 tons, is a single-screw ship of 14 knots, armed with four 4-inch rapid-fire guns.

Next in size to these are four gunboats. The "Bravo" and "Morales," built by Orlando, in 1903, are sister ships of 1,200 tons displacement, carrying a complement of 150 officers and men. They were designed to steam at 16 knots with 2,600 horse-power, and each is armed with two 4-inch rapid-fire guns, six 6-pounders, and with one 14-inch torpedo tube carried above the water line. These are twin-screw gunboats, and each carries about 200 tons of coal. The other two gunboats are the "Tampico" and the "Vera Cruz," built in 1902 at Elizabethport, New Jersey. Each is of 980 tons displacement, and the complement of officers and men is 98. They can steam 16 knots with 2,400 horse-power, and the armament consists of two 4-inch rapid-fire guns and six 6-pounders, with one 14-inch torpedo tube in the bow above the water.

The other vessels are obsolete, the most important being the "Zaragoza," built in 1891, and rebuilt in 1910. She is of 1,200 tons displacement and steams at a speed of 15.5 knots. Her armament consists of six 4.7-inch, rapid-fire, Schneider-Canet guns. The navy is also credited with a transport, the "Oaxaco," and possibly three or four others. The harbor service vessels are quite negligible, being nearly forty years old.

Mercury and X-Rays

RESEARCHES have recently been made by Landau and Piwnikiewicz on the phenomena of luminescence produced by X-rays acting on mercury vapor, particularly as regards the relation between the luminescence and the nature of the rays. The luminescence of mercury does not occur except at high temperatures. On making a vacuum in a glass vessel containing mercury and heating it and exposing it to the X-rays, an intense bluish green fluorescence is observed. Appropriate diaphragms permit one to limit the sheaf of rays, and, in consequence, the luminescent surface. The authors observed that the fluorescence is accentuated as one increases the density of the vapor, while the addition of foreign gases diminishes the intensity of luminescence, of which the emission spectrum is continuous. The authors explain these phenomena as follows: The energy of the X-rays being absorbed by the vapor, the increase of intensity resulting from an increase in density is easily understood. The atoms of mercury emit secondary kathode rays, to which the strong ionization is due. Now, the presence of a lighter foreign gas causes these secondary kathode rays, by successive molecular shocks, to pass, for preference, across the lighter gas, which necessarily enfeebles their effect upon the molecules of mercury.

Kathode Rays and the Tail of Comets

FOR some time the luminosity of cometary appendages has been attributed to electrical phenomena analogous to those which take place when a tube of rarefied gas is traversed by an electric discharge. But this rather vague explanation took the second place when Arrhenius came forward with the theory that the tails of comets are due to the pressure of radiation from the sun. But another explanation has been offered recently which is, from some points of view, more satisfactory. The nucleus of a comet is regarded as a permanent source of electrons which are projected into the cometary atmosphere. If now the electric field of the sun is centripetal, the luminous effects, due to the projected electrons, should be localized in the direction opposed to the sun. From researches made on the magnetic field of the sun, and applying the theory of Schuster, which attributes the magnetism to electric charges carried round by the sun's rotation, it appears that the dominant electric charge on the sun should be negative, which results in a centripetal electric field; thus, the above hypothesis accords with the most recent discoveries.

The Degeneration of the Arab Horse

THE Arab horse, a race which has been all-important in the development of the most valuable equine breeds of the present day, is said to be deteriorating in quality and diminishing in numbers in its original home, owing to changing habits of the Bedouins and increasing exportation. The *Philippine Agricultural Review* states that as a step toward preserving this famous breed there is being formed in Cairo an International Horse Society. The first work of this society will be to start a studbook, one part of which will include only pure-bred horses of desert origin, while the other will be open to all so-called "eastern" horses; i. e., horses bred in the near East, but having an infusion of alien blood. Pure-bred Arabians are now found only among the different Bedouin tribes of the Arabian and Syrian deserts (in Mesopotamia and the Nejd); in a few private studs in Egypt; and in a very few European and American studs. The society will hold annual shows and auction sales at which will be offered animals of certified purity of pedigree.

Kerosene Motor Competition Postponed.—The kerosene motor competition, which was to have been started by the Automobile Club of France, Paris, on October 1st next, has been postponed. It will take place commencing November 15th.

Engineering

Four One-Thousand-Foot Drydocks Built and Building.—There are now four drydocks of 1,000 feet in length built or under construction. The Gladstone Dock, 1,000 feet long, has been completed at Liverpool. Another is being built at Quebec, and a third at Boston. Last month the Hughes drydock at Bombay, India, 1,000 feet long, 100 feet wide, with a depth of 30¼ feet, was opened.

Lives Saved by Street-Car Wheel-Guards.—The Public Service Commission states that recently, in three days, eleven persons were run down by street cars, and that ten of them were saved by the operation of the wheel-guards. These guards were installed by order of the Commission, and their saving of human life has been proved time and again. In one case two boys were picked up together; at another time an elderly man was saved from passing under a car, with no greater hurt than a few bruises.

Subway Carries Two Billions Without a Fatality.—The Interborough Rapid Transit Company, which operates the New York Subway, points with justifiable pride at the fact that the present subway has transported 2,198,000,000 persons in the last nine years without a single passenger fatality, and this in spite of the fact that the speed and frequency of this train service is unsurpassed in work of this character. The subway is undoubtedly the most efficiently operated railway system in the world, and there is no doubt that this wonderful record for safe travel is, on the mechanical side, mainly attributable to the efficiency of the automatic stop.

Demolition of the First Sky Scraper.—There has recently been demolished, to make way for a larger structure, a ten-story tower building, at 60 Broadway, New York city. The building was erected in 1889 and has been in service for a quarter of a century. Naturally the condition of its framework was a matter of interest for architects and engineers. The frame consisted of cast iron columns and wrought iron floor beams. The floors were of flat-arch, terra cotta construction. The framework was found to be in excellent condition, the wrought iron beams showing a practical absence of rust, and the cast iron columns, with a three-inch cast iron shell around them for fire protection, showing only a few localized patches of rust and heavy rusting only at a few special points.

Reconstruction of the Lachine Bridge over the St. Lawrence.—The once notable Lachine Bridge of the Canadian Pacific Railway over the St. Lawrence River near the Lachine Rapids, about seven miles above Montreal, has recently been renewed and double-tracked. The old single-track bridge, built in 1885-1887, consisted of two channel spans, each 480 feet long, and deck spans 80 to 270 feet long. An interesting feature of the channel spans was that they were connected to the adjacent 270-foot spans by curved connecting chord-pieces, thus making the four spans continuous. The old bridge was designed for a loading which was only about one half of the train load for which the new bridge has been designed—an eloquent commentary on the rapidity with which the weight, power and capacity of our freight train service has increased in the last quarter of a century.

The Beaufort Scale of Wind Velocity.—The Weather Bureau, which is under the United States Department of Agriculture, has announced that on and after April 1st it will utilize the Beaufort wind scale to designate the velocity in all wind forecasts and storm warnings. The Beaufort scale as thus announced is as follows:

Force.	Destination.	Miles per Hour
0.	Calm.	From 0 to 3
1.	Light air	Over 3 to 8
2.	Light breeze	Over 8 to 13
3.	Gentle breeze	Over 13 to 18
4.	Moderate breeze	Over 18 to 23
5.	Fresh breeze	Over 23 to 28
6.	Strong breeze	Over 28 to 34
7.	Moderate gale	Over 34 to 40
8.	Fresh gale	Over 40 to 48
9.	Strong gale	Over 48 to 56
10.	Whole gale.	Over 56 to 65
11.	Storm	Over 65 to 75
12.	Hurricane	Over 75

A Movement for Good Roads.—The American Highway Association and the American Bar Association have inaugurated a movement to remove from the statute books of various States, ancient and obsolete road laws which have been on those books more than one hundred years. The first step in the revision of the State road laws would be to recommend that all obsolete and unnecessary laws be rescinded. Certain basic features of good administration will be urged by the joint committees, such as payment of road taxes in cash, elimination of unnecessary officials, the requirement of skilled supervision in construction and maintenance, constant employment of highway engineers, the substitution of appointed for elected officials and the substitution of continuous maintenance for the present intermittent methods.

Science

A Statue of Dr. E. A. Wilson, who perished with Capt. Scott in the Antarctic, is to be unveiled some time next July at Cheltenham, England, Dr. Wilson's birthplace. The statue is the work of Lady Scott, and the unveiling ceremony will be performed by the veteran explorer Sir Clements Markham.

Phosphates in Egypt.—We learn from the *Bibliothèque Universelle*, that vast deposits of phosphate have recently been discovered in the valley of the Nile, on the coast of the Red Sea, and in the oasis of Dakhla. They are composed of fossils and contain impurities consisting chiefly of silica and various salts of iron. The largest beds are at Dakhla, and have a thickness of 2-3 meters, with a width ranging from 4-5 meters to a kilometer and a half.

The International Seismological Association will hold its third general meeting, coincidently with the fifth conference of its Permanent Commission, at St. Petersburg, early in September, under the presidency of Prince Galitzin. The preliminary programme, just distributed, shows that among the principal topics of discussion will be terrestrial tides, together with related questions, such as the elasticity of the earth's crust. A somewhat novel field of discussion will embrace the various possible relations of earthquakes to electrical and magnetic phenomena.

Explosive Dust in Mills.—The engineers of the U. S. Bureau of Mines have, during the past year, investigated every mine coal-dust explosion in which more than two lives were lost. As an auxiliary line of investigation the Bureau has undertaken a study of other inflammable dusts. One investigation related to a grainmill explosion at Buffalo in which 33 lives were lost, and a co-operative arrangement has now been made with the National Milling Association for carrying out further studies of inflammable dust in mills, the cost of the work to be borne by the association.

Lessening Fatigue.—It is well known that it becomes fatiguing to carry a heavy weight in the hand, such as a valise, for any considerable distance, especially because it hinders the movement of the lower limbs. A Frenchman has found a way to prevent this inconvenience, which is as simple as it is practical, and all that is needed is to put under the arm a bulky packet, which is made up of a dozen newspapers folded together. In this way the handbag is far enough removed from the legs so as not to hinder walking with ease. He says that the fatigue is much less and the weight appears to be lighter.

Hailstorm Insurance.—Statistics for the year 1911, recently published, show that the custom of insuring crops against hail is much more prevalent in Germany than in any other country. The total amount of hailstorm insurance carried in Germany in that year was $825,000,000, as compared with the following amounts in other countries Austria-Hungary, $202,500,000; France, $193,750,000; Italy, $100,000,000, Roumania, $100,000,000; Argentina, $62,500,000; Denmark, $55,000,000; Sweden, $25,000,000; Russia, $20,000,000; Switzerland, $15,000,000; Netherlands, $7,500,000, Spain, $5,000,000; Belgium, $2,500,000; Bulgaria, $1,250,000. In Bavaria, Austria-Hungary, Bulgaria, and the Canadian province of Alberta this form of insurance is conducted by the government. The premiums for hailstorm insurance are supposed to be based upon the average frequency of hail, and upon the kind of crop insured; some regions being much more subject to hailstorms, and some crops much more susceptible to their effects, than others. In parts of Italy, premiums up to 5 or 6 per cent are paid, while in Argentina they reach 10 or 12 per cent.

The Sanitation Service of Porto Rico, which was organized in 1911, has recently been much improved through the establishment, by the Porto Rican Legislature, of an Institute of Tropical Medicine and Hygiene, the president of which, Dr. W. F. Lippitt, is also director of sanitation in the island. One of the first undertakings of the Institute was to organize a school for sanitary inspectors, in order to provide a properly trained personnel for the sanitary service. To this school were brought last year those young men employees of the service who, by zeal and attention to duty, had shown themselves worthy of promotion and permanent employment, and the classes were also thrown open to non-employees, with the understanding that those who passed the examination would be given preference in future appointments to the service. Graduates of the school are already doing efficient work in various parts of the island, where previously no persons having any knowledge of sanitation were available for appointment as inspectors. This year, the work of the school will be enlarged, to include courses for health officers. So far as known, this is the only school in the world established for the purpose of training an official sanitary corps. The Institute, of which this school is an appendage, will also engage in research work. One of its members, Dr. P. G. Igaravidez, was sent last year to attend the School of Tropical Medicine in London.

Aeronautics

A New Altitude Record for Balloons is announced in a book by Dr. A. de Quervain, describing his recent crossing of Greenland. Two members of his party, Drs. Jost and Stolberg, remained on the west coast, and during the winter of 1912-13 sent up pilot-balloons 120 times from the Danish scientific station at Godhaven, Disco Island. One of these was followed with theodolites from the ground to an altitude of about 39,000 meters (24.2 miles), which exceeds by about 4,000 meters the greatest height ever before attained by any form of aerological apparatus.

The German Air Traffic Bill.—The Reichstag recently took up a bill for regulating aircraft traffic. According to the *Engineer* the bill aims, in the first place, at minimizing accidents, and provides for this purpose that all new aeroplanes and airships are to be first tested on a flying ground. A second part of the measure deals with aerial navigation companies. As no such undertakings yet exist, great freedom is given to the Federal Council to issue regulations on this subject. Finally, the bill regulates by a number of complicated paragraphs, in which the provisions with regard to motor car traffic have for the most part been adopted, the liability for accidents caused by aircraft.

Russian Air Fleet.—The Russian government has drawn up a programme which provides that orders shall be placed for 330 aeroplanes, including 90 Sikorsky monoplanes and biplanes of the ordinary size and 10 giant Sikorsky machines of the type of the "Ilya Mouromets." For the small aeroplanes other than those of the Sikorsky pattern, recourse will be had to foreign types, such as the Farman, Deperdussin, Morane-Saulnier and Voisin. Two aeroplanes will be ordered from the German firm of Rumpler and two from the English firm of Sopwith, and two will be constructed on the system of the Russian Lieut. Kowanko. Besides these aeroplanes, two dirigible airships will be ordered in France and one in Russia. The programme will be completed by the autumn.

Atmospheric Pressure at Great Heights.—It is usually supposed that at great heights the pressure of the air is almost negligible, but the application of an ingenious method indicated by Ramsay gives interesting results. He asserts that the green line characteristic of the spectrum of krypton remains visible under a pressure of 0.000035 millimeters of mercury. Now this green line is found in the spectra of the aurora borealis and it seems to be well established that this exists frequently at altitudes between 100 and 200 miles, and even sometimes up to nearly 500 miles. But krypton is one of the heaviest gases in our atmosphere. It would seem, therefore, that the density of the air at these altitudes is by no means negligible, as whatever the cause may be of the presence of krypton there, it could not remain there unless the air possessed an appreciable density.

A New French Motor. The new Paris-built aeroplane motor known as "E. J. C." differs from the usual types because it uses a double propeller, that is two separate propellers rotating in opposite directions. The motor is of the kind in which the crank-case and six radial cylinders rotate in one direction, while the crank rotates in the other by mutual reaction alone. One double-blade propeller is keyed on the crank-shaft and another of the same kind, but with inverted thread, is mounted on the body of the motor, one screw being just back of the other, and the pair taking an X-shape when seen from the end. The screws are designed so that motor body and shaft take the proper speeds which are needed, there being 800 revolutions per minute for the motor and 1,200 revolutions per minute for the shaft, making a total of 2,000 revolutions per minute. But as the speed ratio varies with the running speeds, a differential is used inside the crank-case, so as to regulate the speed in the proper way. The present motor is of 60 horsepower size.

The Proposed Exploration of New Guinea by Airship, which has already been mentioned in these columns, does not seem likely to be realized in the near future. The original plan of Lieut. Graetz and his colleagues (some of the latter being scientific men of considerable eminence in Germany) was to raise the money needed for the expedition, about $750,000, in the three countries exercising sovereignty in New Guinea, viz., Germany, Holland and Great Britain. It has been found, however, that little interest was felt by the Dutch and British publics in this German project, while even in Germany the raising of funds has not made much progress. Moreover, the German Colonial Office has expressed disapproval of the undertaking, chiefly on the ground that the frequency of thunderstorms in New Guinea would make such an expedition extremely hazardous. Even if successful, it could add nothing to the world's knowledge of the biology, ethnology or geology of the island. The latest plan of the would-be aeronautical explorers is to exhibit their airship at the Panama-Pacific Exposition, and run a series of excursions with it for exposition visitors in order to raise money for their expedition.

The Problem of Our Navy

X.—Making the Navy an Economic Asset

By Hon. Josephus Daniels, Secretary of the Navy

NO memory lives longer in the minds of a people than the remembrance of their past achievements in arms. It is well that this is so, for the inspiration of the past has enabled more than one tiny nation to defy its enemies and preserve its national existence against all comers Yet we need to beware that this undying recollection of ancient deeds of valor does not make us reckless. It is also true that more than one nation, remembering its dead heroes, has beaten its swords into plowshares and forgotten the cunning of war for the cunning of trade, only to find that the deeds of gallant ancestors will not prove effective in defense if we are not prepared. It is well, I think, for our nation to bear in mind, when the spirit of '76 and the memories of the minutemen of Lexington arise strong within us, that we may be, perhaps, over-prone to feel that in our hour of need there will spring up heroic men who, like our ancestors, will conquer because they know not how to fail. Man against man we will have nothing to fear, but to-day it is not only man against man, but machine against machine as well. The man will always be equal to the occasion. For every crisis a man will arise But while the man is greater than the ship, in our day the master man cannot win as aforetime unless we have the best ships and the best guns

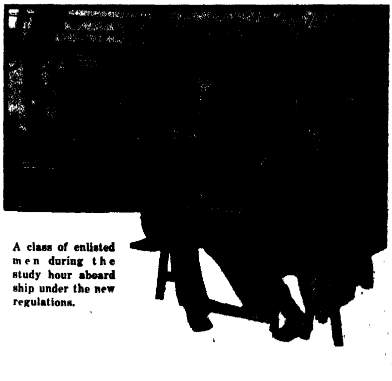
It is this feeling, in my judgment, more than any other, that leads so many of our people to shut their eyes to the cold facts and declare that a nation which in its infancy humbled the pride of England on the sea has no need of floating fortresses of steel to defend it in this, its high noon-tide of mature greatness That such is the view of no small portion of our people cannot be denied. Congress is peculiarly sensitive to what the voters think, and no Congress would have cut our warship construction to one battleship a year in the face of the ambitious naval programmes of other powers had not a majority of the congressmen felt, at the time, that the voters "back home" rested secure in their dream that, in some way or other, dreadnought or no dreadnought, this nation would find some miraculous way of defending our shores against a powerful foe. That a clearer vision came later, and that the people have made it evident to Congress that a majority do not so hold, does not destroy the fact that this misplaced confidence exists in no small degree, particularly in those States far removed from our coasts.

Glories of the Past and Present Necessities.

I speak with greater assurance of this because the same feeling instinctively pervades my own sub-consciousness. Over the mantel by my desk hangs the sword of John Paul Jones; at the other end of the room, the silver urn presented to the great Hull. As I look first on one and then the other, all the cold facts, so ably presented to me by the naval experts—men of the highest scientific knowledge, who have spent their lives in studying this subject—lose, for the moment, their convincing power, and the feeling comes over me that with such men as naval captains a probable defeat upon the sea is foolish to consider. It is only when I turn to look directly across my desk at the model of the "Oklahoma"—so little like the white-sailed ships of the line, so scientifically grim and strong and impregnable, the physical embodiment of the cold science of to-day that aims entirely to eliminate the personal equation—that I again realize that more than a glorious spirit is needed to win a modern fight at sea, although now and always initiative, resourcefulness and courage are a trinity of determining factors in the crisis of battle.

The stricken captain of the next naval engagement will not die leaning against the mainmast, with the shadow of the enemy's sails falling across the deck, rallying his men to repel boarders. He will perish helplessly, in spite of courage unsurpassed, in a conning tower built like a burglar-proof safe, from a shell fired by an almost invisible enemy seven miles away, out of a gun that was pointed by strict mathematical rules after the working out of an elaborate algebraical equation.

I am mentally convinced, as any reasoning man who has studied the subject must be, that our Navy should be strengthened. I subscribe to much of the argument in the series of articles in this paper, to which I contribute this closing number; but if, in spite of the advantages given me by my position to learn the whole truth, it is hard for me to shake off this instinctive feeling that our nation needs no protection beyond its own brave citizens, how much more must those living far inland, whose only knowledge of dreadnoughts comes from the illustrated papers, hold to the view that Providence will protect our country without the need of dreadnoughts, and that an adequate navy is merely a needless national expense.



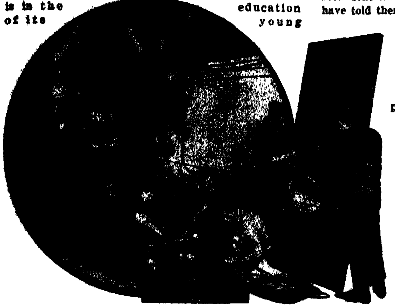
A class of enlisted men during the study hour aboard ship under the new regulations.

The Navy and the People of the Inland.

I sometimes fancy that our naval officers fail to understand the extent and depth of this feeling throughout the country. It is a point of view impossible to men like themselves who, from the day when they entered Annapolis, have had cold facts and figures hammered into them regarding the necessity of a defensive fleet to any country whose coasts are worth the harrowing and whose ports can be made to yield vast tribute to an attacking fleet. Because the popular point of view of this and kindred subjects is impossible for the trained naval man to understand fully, our wise forefathers decided that a civilian should be placed at the head of the Navy, a man who, understanding the feeling of the non-military people, can best adopt measures and frame arguments that will convince them of the imperative need of adequate powers of defense; for I hold that no one can convince until he understands what doubts are to be removed. In my own case, when I became convinced that loyalty, unswerving patriotism, and an exact scientific knowledge of the facts underlay the insistent demands of the Department's naval experts for an adequate Navy, the problem as laid before me took this form: Many people believe that an increase in the Navy is needless. This belief is instinctive and not founded on an investigation of the facts or knowledge of the subject. To convert a majority of these people, it would be useless to publish pages of statistics of numbers of ships, relative displacements, comparative muzzle energies, armor efficiency, steaming areas and kindred data, because the majority of them would not take time to read such tables, nor attempt to understand them if they did. Their gravest objection to an adequate navy is because of their belief that the Navy represents an expense to the Government without compensating benefit in return. The task that lies before the Secretary of the Navy, who understands this feeling on the one hand, but who has become convinced of its erroneousness on the other, is to find some way to secure at least the passive support of these people.

Can the Navy Be Made "Practical"?

Such being the problem, it would seem that if a way could be found to convince this portion of our people that the Navy is not merely an expense, but an economic asset to the country and a good business investment of the taxpayers' money, it would go a long way toward a solution of the [illegible] would [illegible] them from a position [illegible] is one of absolute encouragement of a larger naval construction programme. The greatest economic loss to the country from the Navy, be it necessary or unnecessary, lies not in the money spent, but in the 50,000 men taken from gainful industrial pursuits; for the money spent on the Navy, it must not be forgotten, goes back again into the taxpayers' pockets, to a very large extent. The Navy is not like the rich American who goes abroad to spend his money, but the funds appropriated are used to pay American workmen and American merchants and American manufacturers, and is, in time, distributed among other American citizens, so that, in the end, practically all of it gets back into the taxpayers' pockets from which it came; but if the country loses the productive services annually of 50,000 men, it is a real economic loss without compensation. Now, it is practically universally admitted by students of economics and political economy that the best investment a great and powerful nation like our own can make is in the education of its young men, particularly along industrial lines, and that the nation which has the most efficient and well-trained citizens, skilled to use their heads as well as their hands, is most certain to win in the fierce competition for the world's industrial supremacy. On this point, the theorists and legislative bodies of the great nations of the world are agreed, if the legislation in all these countries in the last few years means anything.



Electrical school, Navy Yard, New York.

Naval Appropriations for Education.

You do *not* hear of legislative bodies in our country, or in any other, squeezing to the last degree appropriations for education; and in Germany, which is one of the leaders in all scientific and industrial movements, provisions for the education of the workman along the lines of his profession are being constantly increased. In our own country, he would be a brave congressman who would dare to say that the hundreds of millions spent by the taxpayers on our public schools was a wasteful extravagance or a needless expenditure of money. If, therefore, it is necessary to make our Navy not only a proper protection to our country, but an economic asset as well, if we would gain universal support to its proper upbuilding, and if the real economic waste of our Navy at present is in the men withdrawn from industrial pursuits to man our ships, why cannot the result aimed at be achieved by taking these men during the time they are in the service of the Navy and training them to the highest degree, so that on their return to civil life they will become a hundredfold more efficient industrial units than they were before?

Yeomen's school, Mare Island, California.

If we can do this, it seems to me we will make the Navy in times of peace a national asset that will be well worth the money. I feel that the Navy presents a great opportunity and should play a great part in the training of our young men. Consider the situation! Here are 50,000 young men, in part suffering from the handicap of limited educational opportunities, and in part, of the type which makes the poorest industrial unit, the type that chafes at the strict discipline of home and factory, and that likes to wander abroad and see new things. If the Navy can take these men, advance their school-book education while, at the same time, training them in discipline, until they realise that to command they must first learn to obey, and in addition, can train their hands to be skilful in the industrial arts, it will surely be something really worth while.

What the Secretary of the Navy is Trying to Do, and Why.

I am not, here, discussing the necessity for increasing the Navy in any case, but of trying to turn what some consider a necessary evil into an important factor in the development of the nation and, in so doing, securing the support of those who remember only John Paul Jones and forget what happened to an inferior fleet, though manned by brave men, at Santiago. I have tried to elaborate in detail the reason underlying my efforts to make the Navy a great school, as well as a greater enforcer of the peace. As for the details of what has been done along these lines, the newspapers have told them in full; the daily classes for *the sailors, the technical* training and opportunities to learn a useful trade now offered all enlisted men—all this has been printed many times.

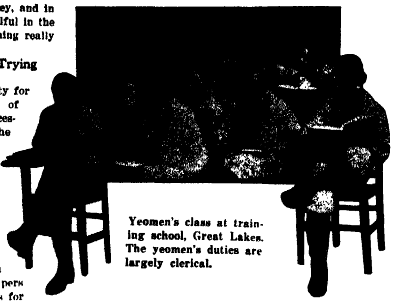
My purpose here is to make my reasons plain. There have been many merry quips by newspaper paragraphers, and sometimes a serious misunderstanding of the aims of this new policy, and I would like the public to understand just what the present Secretary of the Navy is trying to do and why. To the question: Has this plan, so far as it has been in operation, given evidences of success? The best answer lies in the enlistment figures. I have had prepared a chart showing the enlistments this year as compared with the year previous, which is reproduced for the first time with this article. It will be noted that from the 4th of March, 1913, until April of that year, the rapid decline in enlistments of the year previous continued. In April it was definitely published that the fleet would visit foreign shores, and I then announced that it was my purpose to add what has been described as the "liberal education of travel" to my other educational plans for the seamen of our Navy. In the next two months the enlistments increased far beyond the highest point of the year previous.

After the fleet had sailed, the enlistments naturally dropped off, though to nowhere near the low point of the year before. In November, the details of my educational ideas were made public, and were commented upon generally by the papers. From 1565 enlistments in November, there was a jump to 2,000 enlistments in December, breaking all records in times of peace. Could better answer than this be made to the question?

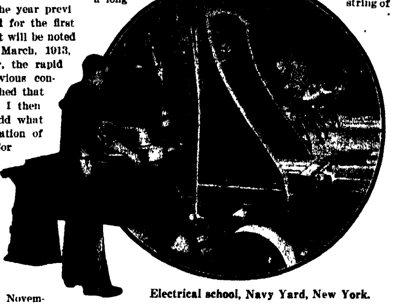
"An Adequate Navy Large Enough and Powerful Enough to Make War with the United States too Unpleasant in Its Consequences to be Seriously Considered."

There are still many details to be worked out, but, so far, no serious objections have arisen to the accomplishment of my dream—an adequate navy, large enough and powerful enough to make a war with the United States too unpleasant in its consequences to be seriously considered by any foreign power, and, at the same time, a navy that will receive young boys with untrained habits and little technical skill and transform them into young men trained to discipline, physically fit, and possessed of a practical knowledge of technical mechanics, that will enable them to bear more than their share of the work of making our nation the greatest in the world. If this policy is successful, if this dream comes true, *may* we *not* claim that our Navy is *no* longer a necessary, though regrettable expense, but is, in reality, in a large sense an economic asset to our country?

An Automatic System of Calling Cabs, known as the "Autoruf" system, is described by the American consul general at Hamburg, where the system has recently been installed. Machines bearing an external resemblance to letter-boxes have been placed in all parts of the city, and are connected by wire with a central office. These machines serve as cab-stands, though it frequently happens that there is no cab at the stand. In the latter case a customer who wants a cab deposits a coin (one mark) in the machine, and his call is automatically signaled to the central office, which sends him a cab from the nearest stand at which one is available; the money deposited is credited toward his fare. The presence or absence of cabs at every stand in the city is indicated on dials at the office by another automatic device, and each of the machines is provided with a calling-horn and a telephone, by means of which orders are transmitted from headquarters. Cabs summoned by telephone to a customer's home, office, etc., are also sent from the nearest stand by this system. The whole plan insures both economy and efficiency of operation, as it enables cabs to be moved about promptly wherever they are needed, and reduces the total number necessary for the business of the city. It no longer happens, as formerly, that some stands have a long string of idle vehicles, while others, where cabs are urgently wanted, are bare.



Yeomen's class at training school, Great Lakes. The yeomen's duties are largely clerical.



Electrical school, Navy Yard, New York.

The Biological Survey and the Forest Service have been co-operating in the extermination of ground squirrels on national forests in California. The annual loss of range feed and grain crops from ground squirrels is enormous.

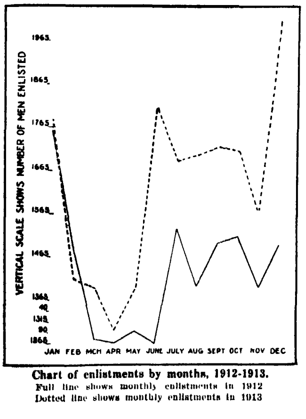


Chart of enlistments by months, 1912-1913.

The Red Coloring Matter of Radishes

To the Editor of the SCIENTIFIC AMERICAN:

I have been investigating the red coloring matter that is found in the skins of radishes and apples and in geranium blossoms. What is its name, and chemical formula?

It is an indicator, orange red in acid solution, and lemon yellow in alkaline. In changing from the red to the yellow it goes through reasonably well defined crimson, purple, and green stages. How do you account for this color change?

It seems to be very sensitive, abundantly found in nature, and easily extracted. Why is it not generally used as an indicator?

I have been unable to find anything about this very interesting coloring matter in any of the botanical and chemical reference books to which I have access, and I hope you can give me a little light on the subject. If no extensive research has been made along this line, I intend to investigate further. A. M. P.

Waxahachie, Texas.

Tapping a Telegraph Cable

To the Editor of the SCIENTIFIC AMERICAN:

The writer is in charge of an engine-room which happens to be built close to where a telegraph cable leaves the shore for England.

Before they enter the cable the telegraph wires are carried overhead from the island post office and pass within five feet of this building.

In the course of experiments the writer found that it is possible, by merely connecting a telephone receiver to any part of the engine and connecting the other terminal to ground, to read the Morse code messages passing on the wires outside.

An iron air pipe connected with the engine and passing overhead, within the building, for about 20 feet and then dropping downward into the earth seems to be the means by which these inductive messages are received.

Having proved the possibility of picking up messages in this way the writer has no further desire to continue the experiment, which is of interest as showing what it is possible to do, sitting inside a building, with no outside connections whatever.

On one occasion a message from the local post office was read, passing to London, announcing the sailing of a certain vessel.

Confirmation of the correct reading of the message arrived a few minutes later, when the ship referred to was seen sailing outward. EDWIN O. CATFORD.

Platte Fougère Lighthouse, Guernsey, England.

The Tide Predicting Machine

To the Editor of the SCIENTIFIC AMERICAN:

In view of the general tone of an article appearing in your issue of March 7th, entitled "A Great Brass Brain," and other articles of like import which have appeared from time to time, I deem it my duty to take this occasion to state publicly that the fundamental conceptions which distinguish this machine from all other tide-predicting machines did not originate with Mr. Fischer, but with myself. So far as comparisons are legitimate, it may be said that my part in the creation of the "new" or "simultaneous" tide-predicting machine is quite analogous to Ferrel's part in reference to the machine which is associated with his name. Mr. Fischer's part was that of a detailed designer rather than that of the original inventor.

One of the items of evidence which may, with propriety, be noted here is the following:

In the Coast Survey Report for 1894 (Part II), pp. 181, 182, I gave a brief description of a machine designed to carry on simultaneously all operations required in tidal prediction. This may be regarded as the first description of the new machine. It was written before the Survey took up the consideration of the construction of a machine. R. A. HARRIS.

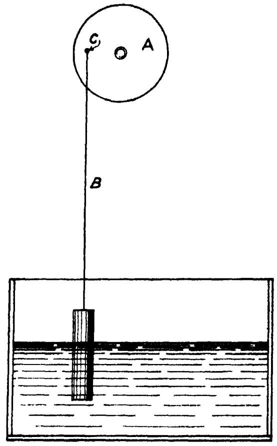
Washington, D. C.

Suggestion for Tide Predicting Machines

To the Editor of the SCIENTIFIC AMERICAN:

I was much interested in Mr. C. H. Claudy's description of the United States tide predicting machine, No. 2, under the heading of "A Great Brass Brain," which appeared in your issue of March 7th. A simple method has occurred to me whereby the construction of such a machine could be greatly simplified, and the chain eliminated, which Mr. Fischer strove to do without success.

Imagine a revolving disk *A* provided with an adjustable eccentric crank *C*, from which hangs a metal cylinder by means of the thread *B*. This cylinder dips into a basin of water or oil or mercury. As the disk revolves the cylinder moves up and down, and the level of the water rises and falls accordingly. This represents one component of the tide, but we may have any number of these units working independently at the same time to represent the other components. The sum of their varying motions will be exactly represented by the varying level of the water in the basin. In other words, the real tide will be reproduced in miniature in the basin. A graphic record of the tide could be made by means of a float with a stylus attached.



Producing a tide in miniature.

Detroit, Mich. N. P. LEVIN.

Solar Halos

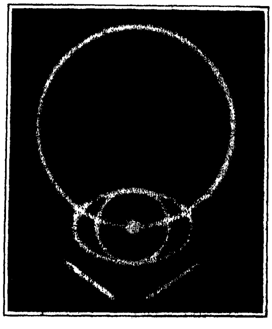
To the Editor of the SCIENTIFIC AMERICAN:

The letter in your paper of February 7th, 1914, from E. C. L. Miller, giving an account of some halos about the sun, recalled to my mind a set of somewhat similar ones that I saw from Nonquitt, Mass., at about 10 A. M. on September 14th, 1900. They struck me as so remarkable that I made a rough drawing of them in my diary at the time, a copy of which I send you.

All the lines were more or less rainbow colored and were especially bright where the lines touched each other. EDWARD M. STETSON.

New Bedford, Mass.

[The study of solar and lunar halos, one of the most interesting byways of science, appears to be enjoying renewed popularity in this country owing to the impression created by the remarkable and widely observed halos of November 1st and 2nd, 1913. This is especially gratifying for the reason that, owing to the comparative rarity and the evanescent character of such phenomena, the perfection of the still fragmentary theory of halos depends upon the collaboration of a large number of painstaking observers. The more persons there are who maintain a vigilant lookout for halos, and prepare accurate drawings and descriptions of those which they see, the greater amount of material will there be for the use of the specialist in dealing with the, at present, obscure questions relating to this branch of optics.



Halos seen on the morning of September 14th, 1900.

S, the sun; *AB*, a large circle parallel to the horizon; *EF*, a circle around the sun; *CD*, an ellipse tangent to *EF* at the top and bottom points; *G* and *H*, two straight rainbow colored lines.

For the encouragement of persons who have a mind to take up halo-observing as a hobby it may be remarked that most varieties of halo are far commoner than they are generally supposed to be, even by meteorologists and physicists. This fact is strikingly illustrated by the records of the Montsouris Observatory, in Paris, where halos are probably observed more assiduously than anywhere else in the world. Thus the commonest of halos—the circle of 22 degrees radius around the sun or moon—was seen at Montsouris on 1,317 days in ten years; an average of one observation every three days. The ordinary parhelia, or sun-dogs, were seen one day in twelve; and the beautiful circumzenithal arc, with its brilliant rainbow colors, one day in 33.

In Mr. Stetson's drawing, herewith, *AB* is the parhelic circle; *EF* is the common 22-degree halo; and *CD* is the circumscribed halo. The lines *G* and *H*, which he has drawn straight, but which really have a slight curvature, with convexity toward the sun, are the extremely rare infralateral tangent arcs of the 46-degree halo; these were observed only twice at Montsouris in ten years.

A comprehensive description, with diagrams, of the known forms of halo was published in SCIENTIFIC AMERICAN SUPPLEMENT, No. 1924, and will be sent to any address for 10 cents.—EDITOR.]

The Canadian Society of Forest Engineers

To the Editor of the SCIENTIFIC AMERICAN:

In your issue of March 28th, you have a little news note in regard to the election of Dr. B. E. Fernow to the presidency of the American Society of American Foresters. In this you say, "This is the only organization of professional foresters in the Western Hemisphere." Will you kindly correct this, as we have also a Canadian Society of Forest Engineers, which was formed in 1906, which has fifty active members and some fifteen associate members, Dr. B. E. Fernow being president; R. H. Campbell, Dominion Forester, vice-president; and myself as secretary.

Grand Mère, P. Q. Canada. ELLWOOD WILSON,
Superintendent of Forestry Division.

Motor Car Speeds and Falling Bodies

To the Editor of the SCIENTIFIC AMERICAN:

The SCIENTIFIC AMERICAN has been the source of much valuable information relating to danger incident to different modes of travel, and since so large a majority of the people now ride (and speed) in automobiles, a hint to them of danger that but few people realize, may interest its readers.

The following computation is designed to compare the speed of an automobile (or other vehicle), as seen by the speedometer registering "miles per hour," with the velocity of a falling body, passing through space at exactly the same rate of speed. From the following table it may be seen that a rate of 40 miles per hour (for example) is exactly the same velocity that a falling body attains from a height of 53.78 feet, under the law of gravity. In other words, a direct impact in a wreck at a speed of 40 miles per hour, is the same as one would sustain by falling 53.78 feet. A striking impression may be afforded any person, by standing on the top of a battlement 53.78 feet high, and contemplating jumping off; and yet, his impact at 40 miles per hour would be the same.

It may be observed from the formula from which this table is computed ($d = 0.03361m^2$) that the danger increases as the square of the number of miles per hour:

d = the height of the fall,

m = the miles per hour one is driving.

Sixty miles per hour (a common boast of "Joy Riders") would be equivalent to a fall of 121 feet.

10	miles	an hour	equals	a fall of	3.36	feet

The Guns of Panama.

The Powerful Defenses at the Terminals of the Canal

By Charles M. Maigne, U. S. A.

THE integrity of the Panama Canal is, of course, of more importance to the United States than to any other country.

Built by money and brains, furnished by our people, the comity of nations demands that its use and benefits be extended to the world at large in the interests of development and commerce; so upon its completion, in time of peace, the great gates will swing open in welcome to any vessel which sails the seas and pays the toll which must be exacted for the maintenance of the waterway. The laws and customs of the civilised world and the precepts of international law are primarily for the preservation of peace, at home and abroad. Peace is the rule and war is the exception, and that the world at large may reap the benefits of the canal the relation of other countries with the United States must be amicable. To the merchant marine and the squadrons of friendly powers, then, the canal stands for peace.

But there is a deeper significance to this country underlying the toil and trouble, the money and men which have gone into the making of this gigantic engineering triumph.

The shifting courses of war may never be forecasted, and it is easily conceivable that from a tiny spark of difference between us and some other first-class power, a cyclone of events and popular opinion might readily fan a blaze of war which would bring to our coastline a foreign fleet, less powerful than our Atlantic and Pacific fleet combined, but superior to either alone.

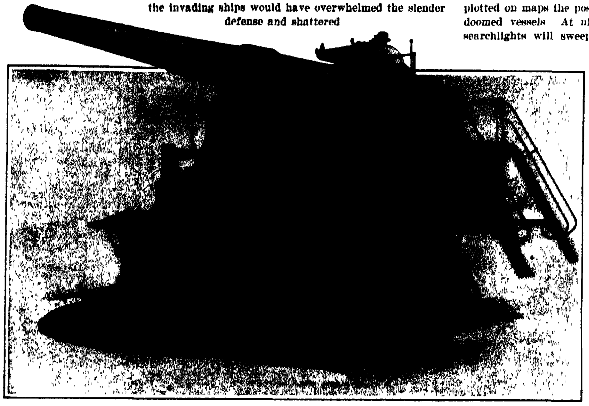
The successes of the greatest military genius who ever lived, Napoleon Bonaparte, were founded upon dividing an enemy superior in numbers and overwhelming the severed wings in detail. Strategy, whether of the land or sea, has not changed in its fundamental principles with the perfection of modern armament; and to prevent the junction of our Atlantic and Pacific fleets, a foreign squadron, to win its way, must strike promptly and strike hard at the Panama Canal

Panama Canal is Greatest Naval Strategic Point in Whole World.

History shows us that the outcome of wars has laid low the might and majesty of many a powerful nation, has even swept the very individuality of a mighty people into an absorption by the conquerors, and left but a tarnished name on its pages to tell of past glories. What has been may be once again. For where would our engineering feats, commerce, wealth, unity, our country, stand if an enemy's mail-shod foot pressed us, defenseless and defeated, in to the ground? We should be broken, disintegrated, prostrate at his mercy, our wealth in his coffers, and his flag above our heads. The Panama Canal, the connecting link between our severed squadrons, stands, therefore, in its greatest meaning, to the people of the United States, not for peace, but for war, and to preserve its usefulness to us, against the greatest time of need, it must bristle with guns sufficient to defend it against any possible foe!

To insure that it remains ours we have already shipped to the ports of the Isthmus some hundreds of thousands of tons of steel, wrought into the forms of the mightiest engines of war ever known to man, and with these guns have gone disappearing carriages and ammunition, electrical appliances, and searchlights, shiploads of steel girders and a countless array of cement barrels containing the gray dust from which the concealed gun emplacements will be built.

Suppose the canal were not amply defended. Before the impending crisis of naval battle between the fleets, the invading ships would have overwhelmed the slender defense and shattered it until they could glide into the locks and take their choice of pushing through in an attempt to crush our weaker fleet on the far side, or lay a charge of high explosive within a lock wall or the Gatun dam or wreck the gates, and then decisively defeat our small fleet on this side before our opposite fleet could round the Horn and effect a junction.



Panama Canal Defenses—14-inch breech-loading rifle.

Length, 48 feet, weight, 09 tons; weight of projectile, 1,660 pounds; range, 18,000 yards; penetration, 13 inches

Suppose the canal were sufficiently defended While the foreign fleet was pounding away in a vain attempt to silence our land guns, summoned by wireless, both of our fleets would be hurrying down their coasts to the canal; and, with the army's triumphant guns holding off the enemy, the far fleet would slip through the canal, the junction would be effected, and the enemy crushed by our combined fleets. Let us see how these defending guns will be placed. The plan of the fortifications will not be given out; but ordinary reason tells us that the guns will be about evenly divided between the eastern and western entrances to the canal. The hills near the sea will shadow dun, turf-covered emplacements. Islands, small and large, will each nurse in its breast the sunken mortar pits, also concealed: and it is even whispered that caissons will sink to the bed of sandbars and support artificial islands of concrete and steel in which will be emplaced invisible batteries.

At war's approach, the fairways will be strewn with mines, to be exploded, either on contact with an enemy's hull, or by the pressure of a tiny key in a secluded house, from which telescopes have marked the approach of the hostile ships and where dexterous fingers have plotted on maps the positions in the mine square of the doomed vessels At night, the quiet fingers of great searchlights will sweep over the mine fields, and an attempted raid by small boats will be checked and crushed by the rapid-fire batteries which guard the planted mines

The guns which will constitute the main strength of the defenses will be of various sizes Chief among them will rise the giant 16-inch gun, the most powerful in all the world Then will come the 14-inch rifles, surpassingly deadly, the 12-inch mortars, against whose plunging shells no ship's deck armor may avail, and the 6-inch rapid-fire guns, to cover the mine fields

In the history of warfare there have been guns of larger bore than that of these at Panama. During the civil war, smooth-bores hurled spherical shells of 20 inches diameter, and there is the well authenticated story of a Turkish gun with a bore of 24 inches; but neither of these guns would have the slightest effect against modern armor, and their range was about equal to that of our 30 caliber rifle, now in the hands of each infantryman

The range of the 16-inch gun is about twenty-one miles at an elevation of 45 degrees, and the shell that twists its swift way high above the plane of sight weighs 2,400 pounds. There is no armor in the world can withstand the terrific impact of this mighty missile, propelled by a charge weighing 650 pounds.

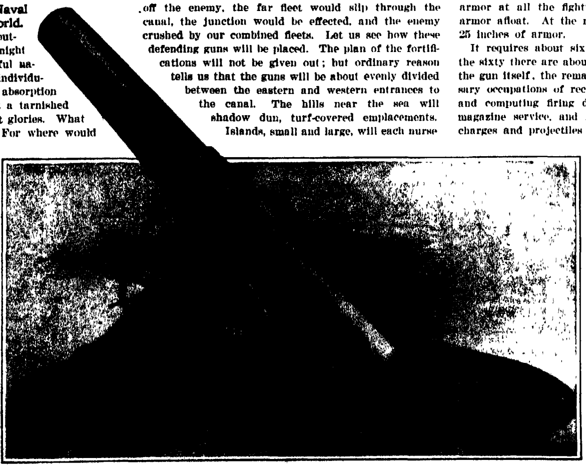
The conical shell itself lacks but two inches of being 6 feet long, is taller than the average man, and it has an average penetration of 17 inches of the hardest armor at all the fighting ranges There is no such armor afloat. At the muzzle, the shell will penetrate 25 inches of armor.

It requires about sixty men to serve this gun. Of the sixty there are about twenty-five actually operating the gun itself, the remainder are engaged in the necessary occupations of receiving the range and elevation and computing firing data, in telephone service and magazine service, and in supplying the gun with its charges and projectiles The service rate of fire, sustained in battle, is about one shot a minute, delivered with marvelous accuracy. It is entirely possible to greatly increase the rate of fire, but any such increase will always be at the expense of accuracy, and a discharge of the gun costs far too much to waste ammunition for the sake of a mere record.

One shell from this gun, with the charge, costing about $1,027.50, should it find its billet, as it probably will, would probably disable a battleship costing in the neighborhood of ten millions of dollars The gun-makers have rather the better of the competition with the armor manufacturers Ships are now carrying about their limit in steel armor

The 14-inch guns, which like the 16-inch will be

(Concluded on page 385.)



Panama Canal Defenses—12-inch mortar.

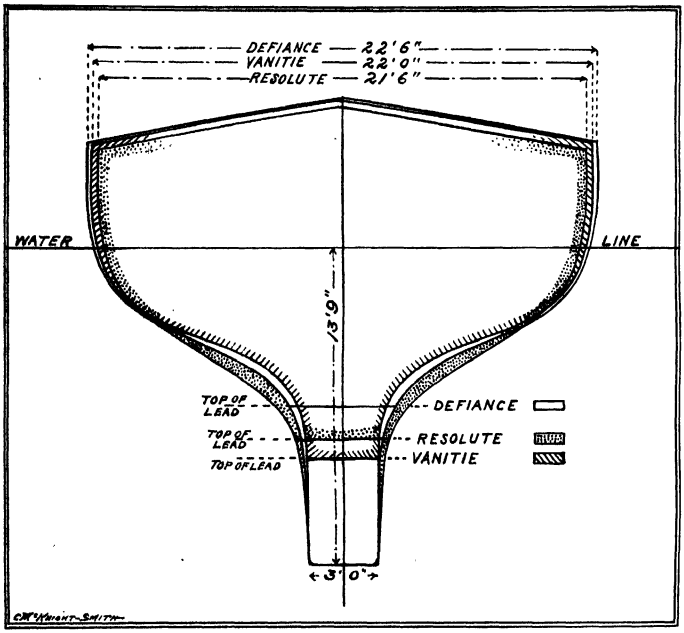
THE THREE CUP-DEFENDERS OF 1914—"Resolute," built by Herreshoff for the N. Y. Yacht Club Syndicate; "Vanitie," designed by Gardner for A. S. Cochran, Esq.; "Defiance," designed by Owen for the Tri-City Syndicate.

The Defense of the "America's" Cup

Construction, Sail Plans and Leading Characteristics of the Three Cup Defenders of 1914

NOW that the British challenging yacht and the three cup defenders are plated up and practically ready for launching, all of them having long passed the stage when any knowledge by the designers of the plans of their competitors, would come too late to have any effect upon the final issue, the SCIENTIFIC AMERICAN takes much pleasure in presenting to its readers the first authentic information regarding the three cup-defending yachts. That so much authentic technical information should be available for publication upon a subject in which the American public is so vitally interested, is an encouraging sign of the times. The old policy of maintaining profound secrecy, long after it has ceased to be necessary, has happily passed away, and the public is to be congratulated on the more liberal and sportsmanlike policy which recognizes the wide-spread national interest in the struggle for the "America's" cup.



Midship sections of the cup-defenders.

New Rule of Measurement.

The three yachts have been designed under the new rule of measurement which will govern this year's series of races. This rule was drawn up with the object of correcting the defects of the old rule. Under the old rule there was a tax on waterline length and sail area and on nothing else. Provided the yacht did not exceed 90 feet on the waterline, the designer might make her as broad, as deep, and as long on deck as he pleased; and he was at liberty to give her as large a sail plan as he wished. In determining the rating of the yacht, that is, the allowance she must give to or receive from a competitor, the waterline length and the sail area, only, were taken into consideration. The greater her waterline length, the larger her sail area, the greater would be the allowance which she had to make over a 30-mile course to her competitors. These were the only restrictions. Working under this rule, it was found that a yacht with a broad, shallow and generally scow-shaped hull, with long overhangs, carrying a great mass of lead at the bottom of a deep keel, and driven by a vast spread of sail, produced the fastest yacht under the average weather conditions off Sandy Hook. The most extreme yacht built under the rule was the "Reliance," which, on a waterline length of just under ninety feet, was over one hundred and forty feet in length on deck, and spread the enormous sail area of over sixteen thousand square feet of canvas. The bilges were hard and carried well out into the ends, the turn at the garboards from the floor into the keel was sharp; and it was the boast of Nat Herreshoff, her designer, that the "Reliance" had the largest sail area in proportion to the wetted surface of the hull of any yacht that had ever been built.

The racing yachts built under this rule lost their usefulness as soon as the cup contests were over. Their spars were too big, and their hulls too shallow, and their draft too great, to render them useful as cruisers; and most of those which were built for the last four series of races had to be broken up and sold for junk.

The changes introduced under the new rule were in the direction of producing a more wholesome boat, with a larger displacement, a smaller draft, a sweeter form with sharp ends—a form which would have a much easier motion in a seaway than the old scow form, which pounded heavily and was extremely wet in going to windward in a short sea.

A comparison of the cross sections of the three challengers of the present season shows the modifying effect of the new rule. The bilges are easy, the deadrise of the floor is steeper and the turn into the keel at the garboards is much fuller than in the yachts built under the old rule. The new rule *favors displacement*; that is to say, the yacht with the larger displacement, other things being equal, will have the smaller rating and the larger time allowance. Considered from every point of view, the cup yachts of the season 1914 are much abler and more satisfactory sea boats than their predecessors of the last four or five contests for the cup. Although the construction is very light, the materials have been so well disposed that the yachts are amply strong for the work they will have to do. Moreover, they will be available, when the races are over, for the regular yacht club regattas which are annually held on our coasts. If their future owners wish to turn them into cruisers, there is sufficient head room to enable the interior of their hulls to be bulkheaded and furnished with the necessary cruising accommodations. A reduction in sail plan can be made without any serious reduction of the speed, and the boats can be handled, under this reduced rig, with crews of moderate size

Points of Similarity and Difference.

In respect of two of the principal dimensions the three yachts are alike. Each is 74 feet 9 inches in length on the load waterline, and the draft of each is 13 feet 9 inches. Also, there is not much difference in the beam, only one foot, in fact, between the narrowest, "Resolute," and the widest, "Defiance," whose width is, respectively, 21 feet 6 inches and 22 feet 6 inches. "Vanitie" comes between with a beam of 22 feet.

Of all the drawings, the most interesting and instructive is that showing the midship cross sections superimposed. From this it will be seen that "Resolute" has the fullest and deepest underwater body, with an easy bilge, steep floor, and a full turn from the floor at the garboards into the keel "Vanitie" shows the least departure from the yachts built under the old rule, and, of the three boats, her bilge is harder, her floor flatter, and she is more cut away at the garboards, where the turn from floor to keel is rather sharp "Defiance" shows a cross-section midway between the two. The effect of these midship sections is shown in the other dimensions of the hulls Thus "Resolute" has much shorter overhangs than the other two boats, both forward and aft, her over all length on deck being only 100 feet 5 inches, as against 115 feet in "Defiance" and 119 feet in "Vanitie" Speaking broadly, it may be said that while the differences in midship section are not very great, "Vanitie" suggests something of the U-section and "Resolute" the V-section, with the "Defiance" midway between the two There is probably not much difference in the displacement of the three yachts, which is something over one hundred tons The Gardner boat, "Vanitie," with her harder bilges shows a more *powerful form* than Nat Herreshoff's "Resolute," and in reaching and running, or at any time with sheets started, she should be the faster boat. In windward work, and particularly in a confused sea, we should incline to favor the chances of "Resolute"

The most interesting feature of difference in the three yachts is the sail plan, and it will come as a matter of surprise that the Herreshoff boat carries a spread of sail which is surprisingly less in area *than that of the* other two yachts, the "Resolute" spreading 8,188 square feet, "Vanitie" 9,465 square feet, and "Defiance" 9,819 square feet, or 1,631 square feet more than the Herreshoff boat The modern tendency to make the rig lofty and relatively narrow is shown in the sail plan of each yacht, and this is particularly noticeable in "Defiance" "Resolute" on a base line of 131 feet has a vertical height from main boom to topmast truck of 125 feet; "Vanitie" on a base of 144 feet 6 inches shows a vertical height of 131 feet, whereas "Defiance" on a base line of 134 feet 6 inches has the enormous height of 146 feet. Both "Resolute" and "Vanitie" carry double headsails, and the division of the base line for the forward and after triangle is about normal practice. In "Defiance," however, *the mast has been stepped far* forward, and the bulk of the sail area is concentrated in the mainsail. Her boom has the enormous length for a 75-footer of 90 feet, as against 85 feet in "Vanitie" and 75 feet in "Resolute" From the forward side of the mast to the end of the bowsprit of "Defiance" is 42 feet 6 inches, as against 54 feet in "Resolute," and 57 feet 6 inches in "Vanitie" It is needless to say that "Defiance" carries only a single headsail

The concentration of so much of the sail area in one large mainsail has been favored by George Owen, the designer of "Defiance," in the expectation of securing fine weatherly qualities in going to windward Theoretically, "Defiance" should point high and foot fast while doing so; but, as everyone who has handled the wheel or tiller of yachts rigged in this fashion knows, she is liable to be a very difficult boat to steer. The

DIMENSIONS, ETC., OF THE THREE CUP DEFENDERS

	Resolute		Vanitie		Defiance.	
	Ft	In	Ft.	In.	Ft	In

possession by "Defiance" of this rig will lend a special interest to the long series of contests which will take place during the present season between these three boats, to determine which of them shall be selected to meet Sir Thomas Lipton's "Shamrock IV."

Construction of the Yachts.

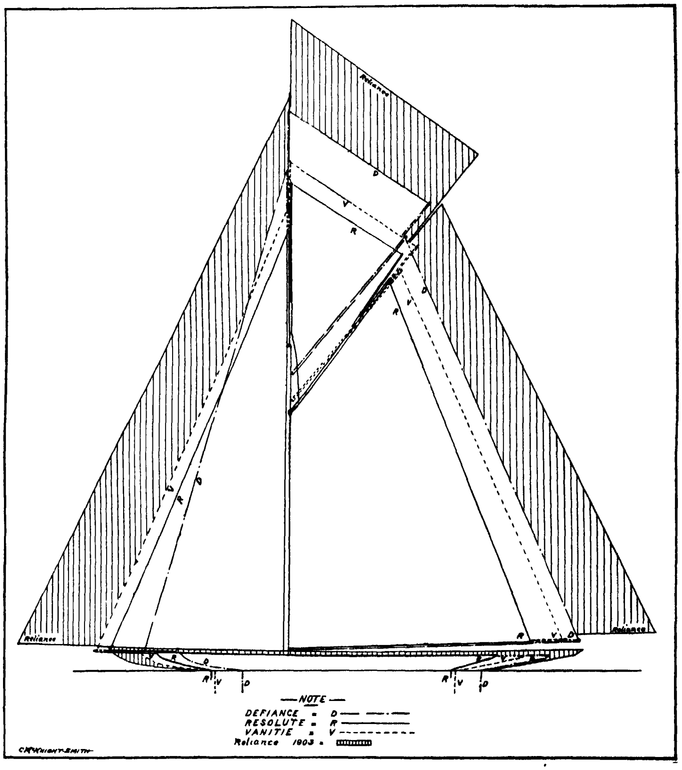
"RESOLUTE"—The construction of "Resolute" follows in general that type which Herreshoff originated in "Constitution" and "Reliance." It consists of a series of deep web-frames varying in depth from 8 to 12 inches, with lighter frames between, and longitudinal framing following the line of the seams of the bronze plating The plating is laid on with flush seams and butt joints It consists of 5/32 inch manganese bronze, and the lowest or garboard strake overlaps the lead 2 feet, the lead being covered with brass sheeting 1/32 inch thick. Intermediate with the deep web frames, which extend entirely around the hull, are shorter and lighter frames, three between each web There are two mast steps, spaced 33 inches apart, center to center The mast is built of nickel steel, stiffened with 2¼ by 1⅛ inch bulb nickel stiffeners. It is 20 inches in diameter at the foot. The topmast, 12 inches in diameter, is of wood, and it foots upon a steel cone within the steel mast and 5 feet below the cap The lead keel is placed between web frames 29 and 45 It measures 26 feet 11 inches on top and is 4 feet 6 inches deep at the heel and 5 feet 6 inches deep at the nose. The length of the lead on the bottom is about nineteen feet. The "Resolute" is decked with aluminium plates 7/32 of an inch thick, the whole deck being covered with canvas, sanded

"VANITIE"—The framing of "Vanitie" consists of web frames 10 inches deep, eight in all, which are spaced as shown in the drawing. The framing extends from the keel plate up to the covering boards, and consists in addition to the web frames of 8-inch by 1¾-inch L-angles. The "Vanitie" is plated with manganese bronze, which varies from 3/16 of an inch to 7/32 of an inch in thickness.

The mast is a hollow steel spar 20 inches in diameter, and the mast step is located between the web frames on stations 27 and 30. The lead keel measures 34 feet on top, and it is 2 feet 10 inches deep at the heel, and 4 feet 6 inches deep at the nose. It is secured to the hull on web frames 38, 41, 46, and 54

"DEFIANCE"—The hull of the "Defiance" is constructed of steel framing, overlaid by two thicknesses of wooden sheathing. There are 73 frame stations, and every tenth station is a deep web frame. This framing is tied together with diagonal straps, 3/16 inch thick by 6 inches wide, riveted to the outside of the frame. The inner sheathing of the hull consists of ¾ inch fir, and this is bolted to the frames with bronze bolts. Upon this is placed the outer skin of mahogany, 1¼ inch thick, which is fastened to the inner skin with bronze screws from the inside The deck plating is of pine. The lead bulb is 4 feet 9 inches deep at the heel and 7 feet deep at the nose, and it measures about 28 feet along the top.

The "Resolute," designed by Herreshoff, has been built by him at Bristol; the "Vanitie," designed by William Gardner, was built by George Lawley & Son, at Neponsett; and the "Defiance," designed by George Owen, was built by the Bath Iron Works, at Bath, Maine.



A comparison of sail plans.

French Artificial Wood.—Information has been made public in Lyons, France, concerning an artificial wood, which, it is stated, will be of great value as a substitute for natural wood. The new product has been found after years of study and practical experiments, the most recent of which have given eminently satisfactory results. The process consists in transforming straw into a solid material having the resistance of oak. The straw after being cut into small pieces is reduced to a paste by boiling, to which certan chemicals are added. When the paste has been reduced to a homogeneous mass it is put into presses, and planks, beams, laths, and moldings of all sizes are readily made. This new material can be sawed like natural wood. As a fuel, it emits a bright flame and little smoke. It is further stated to be adaptable to the manufacture of match stems.

How Bubonic Plague Reached Porto Rico

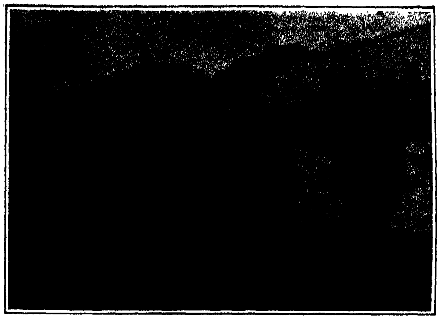
IT will be recalled that an epidemic of bubonic plague occurred in Porto Rico in the summer of 1912, throwing the whole island into a panic and paralyzing business, but fortunately resulting in only a small loss of life, owing to the very prompt and energetic measures taken by the health authorities. The source of this epidemic is revealed in the last report of the Government of Porto Rico, and the revelation constitutes a serious charge against an official health service in another quarter of the world. At first it was suspected that plague had entered the island through the medium of certain shipments of maize from Venezuela, the sacks containing infected rats. Another conjecture was that it had come from the United States on a ship in which two infected rats were found. Ultimately, unmistakable proof was adduced that the infection had been received from the Canary Islands. An epidemic of plague had occurred in the latter islands some time before the first case appeared in Porto Rico, but the Spanish authorities had concealed the fact from the world. Moreover, the health officials in the Canaries have naively admitted that plague had existed there for years, but they thought it best not to divulge the fact! Meanwhile vessels from the Canaries had been allowed to dock freely, without quarantine, at San Juan and at other ports throughout the world.

The Current Supplement

THIS week brings the two thousandth issue of our SUPPLEMENT. Among the principal articles appearing therein is the account of Dr. Bridgman's experiments on water at pressures of 20,000 atmospheres, or 300,000 pounds per square inch. These experiments have brought to light the interesting fact that in addition to the two kinds of ice previously known to science, there are three more, five in all.—Dr. V. Cornish contributes a most interesting article on the dimensions and velocity of ocean waves.—The second instalment of the account of the London Aero Show appears in this issue, accompanied with thirty-two descriptive illustrations.—What is the smallest object visible to us on the moon? This question is answered by Abbé Moreux for our readers.—A thousand-ton forming press for large metal objects is illustrated and described.—C. H. Bromley explains how a carbon dioxide absorber for the automatic registration of flue gas analysis works.—The nature and prevention of dust explosions in coal mines and factories is discussed in detail.—The temperatures in the various parts of a steam plant are traced from furnace to condenser.—Dr. J. H. Barach suggests a dynamic index which measures heart action.—What generator and accumulator equipment is recommended for different circumstances for country house electric power plants? The reader will find this question answered in a special article.—Diagnosing diseases in patients 1,500 years old—such is the task which Dr. Ruffer has set himself. A note on his work will be found on the last page of this issue.

Primitive Mining in Mexico

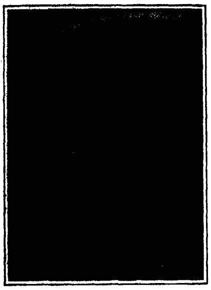
WEIGHING a miner and his load together is the method used by a Mexican company to ascertain the quantity of ore brought to the surface. Of course the weight of each man and his outfit is noted in the weigher's memorandum book, so the amount of ore is figured at a glance. The methods of bringing the ore to the surface are primitive, indeed, compared to the electric hoists used in mines of modern equipment. The group of peons with their rough baskets filled with ore is eloquent of the cheapness of human labor in the mines of our neighboring lands to the south. In some old workings the loads are still raised by the Mexicans, who climb to the shaft's mouth by ladders, bearing heavy baskets or sacks on their shoulders.



To guard against theft, miners in Mexico are weighed with their load of ore.

Teaching Swimming With Trolleys

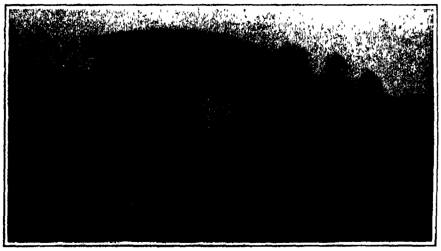
A NEW system of teaching boys and girls how to swim has been instituted in certain Cincinnati schools equipped with bathing pools. An apparatus is employed consisting of an oval track secured to the ceiling over the pool. A dozen trolleys run on the track, and from each depends a rope with a belt attached. Twelve pupils fasten the belts around their waists and the swimming lesson is on. They go through the motions of "sailor fashion" and the "Australian crawl" as per the direction of the swimming instructor, who keeps watch from around the edge of the pool. They cannot sink, so the only thing remaining for them to do is to swim. This "water-merry-go-round" has proven so successful that others like it are to be installed in schools where a bathing pool is a part of the equipment.



A trolley swimming lesson.

Motor Car Locomotive

RECENTLY we illustrated in these columns a touring car used for passenger transportation on a small western railroad. Pictured herewith is another car used for a similar purpose, and also acting as a locomotive for a freight train. It furnishes daily service from Westmoreland to Blaine, Kansas. The rear wheels of the automobile are fitted with flanges to fit the track rails, and the front wheels have been replaced by a four-wheeled swiveled truck. This motor-car locomotive is able to haul three small freight cars. The picture shows the train loaded with six tons of freight.

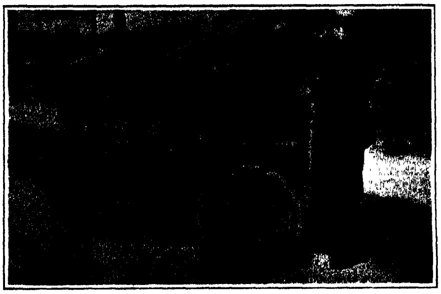


Combination freight and passenger train hauled by motor car.

Up-to-Date Scissors Grinder

IT has often been said that the advent of mechanical operation has killed the small industries, but recent developments in engine design, especially the construction of gasoline engines, are bringing about an opposite tendency, and the individual artisan frequently finds a powerful help in the adoption of such motors for driving his tools, or operating a dynamo which in its turn supplies current to a number of small electric motors.

That even the most humble workman may derive profit from the use of machinery is strikingly shown by the accompanying photograph of a clever scissors-grinder who has recently fitted his grindstone with a gasoline motor enabling him to carry out his work more rapidly and efficiently than his competitors. Not only does the engine propel his machine, but it also turns his grindstone for him.



Scissors-grinder's home-made motor car and power grinder.

England's Oldest Fire Engine

PICTURED in the accompanying engraving is a relic of early fire-fighting apparatus, which is claimed to be the oldest fire engine in England It is kept in the verger's vestry in Malmesbury Abbey The engine is said to have been built in the year 1700, and saw nearly a hundred and fifty years of service It was last used at a fire in Burton Hill House in 1845. In those days things were built to last and machines were not scrapped, until beyond repair. As the photograph clearly shows, it is a hand-pump adapted to draw water from tanks at either side of the pump cylinder, which was located at the center of the machine These tanks were kept filled by a bucket brigade

Fire engine of the eighteenth century.

The 14-inch Guns of the "Texas" and "New York"

ON opposite sides of one of the piers at the Brooklyn Navy Yard, and exactly abreast of each other, are the two latest additions to our Navy, the dreadnoughts "New York" and "Texas," the former built by the Government at the Brooklyn yard, and the "Texas" recently from the hands of her builders at Newport News Both ships are receiving their finishing touches before sailing for Mexican waters The most interesting and novel feature about these ships is their main armament, which, in the case of each ship, consists of ten 14-inch guns. The 14-inch gun has never before been mounted on a ship of our Navy. Preceding the "New York" and "Texas" were the "Wyoming" and "Arkansas," and each of these ships carries twelve 12-inch guns in six turrets. Although the "New York" and "Texas" carry less guns by two, they have a heavier broadside, for the increase of two inches in the caliber means a very large increase in the power of the guns The 45-caliber, 12-inch gun fires a shell weighing 870 pounds with a muzzle energy of 48,984 foot-tons, and it can penetrate 15.2 inches of Krupp armor at 10,000 yards. The 50-caliber 12-inch gun, which is, of course, five feet longer than the one just mentioned, fires an 870-pound shell, with a muzzle energy of 61,644 foot-tons, and it can penetrate 15.6 inches of armor at 10,000 yards. The 45-caliber 14-inch gun fires a 1,400-pound shell with a muzzle energy of 65,687 foot-tons, and at 10,000 yards it will penetrate 15.9 inches of Krupp armor. The penetration, it will be observed, is very little greater than that of the 12-inch, but the bursting charge of high explosive contained in the 14-inch shell is very much larger.

The Heavens in May

The First Comet of 1914, and Its Orbit

By Henry Norris Russell, Ph.D.

THE first comet to be discovered in 1914 was detected by Dr Kritzinger of Bothkamp, Germany, on March 29th It was then on the borders of Scorpio and Ophiuchus, in 16 hours 12 minutes right ascension and 9 degrees 30 minutes south declination, was moving northeastward about 1 degree a day, and was visible in a small telescope. Further observations were promptly secured, and the elements of the orbit have been calculated by Prof Crawford and Miss Levy of the University of California, and by Prof. Kobold of Kiel. The two sets of elements are in very close agreement, and show that the comet will be nearest the Sun on May 31st, at a distance of 1.255 astronomical units, or 117 million miles. It is moving around the Sun in the same direction in which the planets go, and the plane of its orbit is inclined only 25 degrees to that of the ecliptic

The circumstances of its apparition are shown in the accompanying diagram. The comet's orbit must be supposed to lie above the plane of the paper on the left of the line of nodes, and below it on the right—its greatest height above this plane being equal to about half the diameter of the Earth's orbit. The positions of the comet and the Earth at the beginning of each month are joined by lines drawn on the diagram It is easy to see why it was not discovered earlier, for, a month or two before it was first seen, it was farther from the Sun and Earth (and hence much fainter) and also much farther south in the heavens

All through April the Earth gains on the comet, while the latter approaches the Sun, and the combination of these changes causes a rapid increase in its brightness

During May it will be at its best; then it will slowly recede from us and from the Sun, and gradually fade away, though it will be brighter than it was at the time of discovery until the end of August.

The best available ephemeris of its motion now at hand stops on April 30th, on which date its predicted position is in 18 hours 6.5 minutes right ascension and 15 degrees 18 minutes north declination. At this time it is moving 4 minutes eastward and 1 degree northward per day, and its rate of motion is gradually increasing. Allowing for this, it appears that on June 1st it will be in about 20 hours 20 minutes right ascension and 46 degrees north declination; but these are only rough estimates. Its path among the stars lies in Hercules, Lyra, and Cygnus. On May 15th it will be about half-way between β Cygni and β Lyrae.

At the time of discovery it was visible, though not conspicuous, in a small telescope. It will be five or six times as bright as this in May, but it is not at all likely to be visible to the naked eye. Even at the time of discovery, it showed a very faint tail, 40 minutes in length, and when nearest the Sun it will doubtless have a longer one, and be a pretty telescopic object.

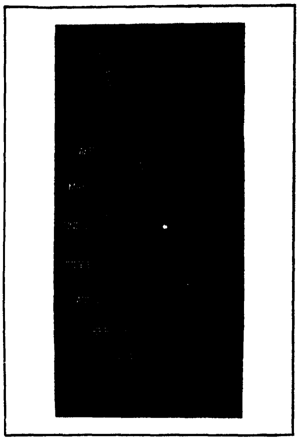
Delavan's comet, which is still behind the Sun, and almost unobservable, was brightening up rapidly when last seen, and will probably be conspicuous in the autumn

The Heavens.

The student of our evening skies may well begin this month by looking right overhead. There, so high that at a first glance he seems almost in the zenith, is the great red star Arcturus, one of the most splendid objects in the heavens. He is conspicuous to the eye for three things, his great brightness, his isolation—no other star at all comparable in brightness with him being within 30 degrees distance—and his red color Viewed with the telescope his brightness and color are, of course, far more impressive; but, even with the most powerful instruments, he remains but a point of light, showing no sign of duplicity, either to direct observation or to the spectroscope. Measurements of his position in the heavens show, however, that he is moving southwestward among the other stars, at the relatively very rapid rate of 2.28 seconds per year. Since the time of Ptolemy, he has moved through more than a degree. This may seem a very small change to happen in 1800 years; but when we pass from the apparent to the real motion of the star, we come upon a speed which no one could call slow.

The parallax of Arcturus, according to the final result of the long series of measurements made at Yale, is 0.075 second. That is, its distance is 2,750,000 times that of the Sun, or 43 light-years, and we see it now as it was in 1871.

Upon computing its actual rate of motion, we find it to be 90 miles per second, or in more familiar units, 324,000 miles per hour. Spectroscopic observation shows that this motion is almost exactly at right angles to our line of sight toward the star; the rate at which it is approaching us is between two and three miles per second



Orbit of Kritzinger's comet.

If removed to the distance of Arcturus, our Sun would appear as a star of the fifth magnitude, just comfortably visible to the naked eye. Even the dazzling Sirius, if set beside Arcturus, would appear as a relatively faint companion, only one fifth as bright as he; for Arcturus is 115 times as bright as the Sun.

Why should this star be so bright? Is it because of its great size, or of high intrinsic brightness of its surface? A pretty definite answer can now be given to this natural question. Arcturus is a red star, and both the color of his light and the behavior of certain lines in his spectrum afford very good reason to believe that his surface is not as hot as the Sun's, though still probably hotter than the hottest electric furnace. If his surface is cooler than the Sun's, it will give out less light and heat per square mile; according to the best estimate we can make, from one third to one fourth as much. But it gives out altogether 115 times as much light as the Sun; so it must have somewhere between 350 and 450 times as many square miles in its surface as the Sun has; that is, its diameter must be not far from 20 times that of the Sun.

Though Arcturus must exceed the Sun in bulk several thousand times, it is very improbable that he surpasses the Sun in mass to at all the same degree. We have no way of getting at the facts in this particular case; but in many similar cases it can be shown that stars of similar brightness, color, and probable diameter contain but a few times as much matter as the Sun. Such stars are of very low density—sometimes not more than that of air—and must be huge masses of rarefied incandescent gas. It may be hard to believe that a mere mass of hot air, however big and hot, could shine far more brightly than the Sun. But air is not quite the perfectly transparent substance that we suppose. Ten miles of it will cut out fully one quarter of the intensity of a beam of light, even on the clearest days; and, at this rate, a thousand miles of air would be practically opaque, and five thousand miles of it would quite conceal the Sun. A ball of gas, millions of miles in diameter, seen from a great distance, would behave like an opaque sphere, except at the very edge, and, if heated, would shine brilliantly.

Below Arcturus, rather to the right, we see Spica, in Virgo, which looks fainter than Arcturus, but must be at least four times as far off, and is really much brighter. Lower down is Scorpio, some of whose stars are still more remote and equally bright or brighter.

Due south, almost on the horizon, appears a part of the southern constellation Centaurus. Its two brightest stars, α and β Centauri, the former our nearest neighbor in space, can now be seen close to the horizon from points in Florida and southern Texas.

Ophiuchus and Serpens fill the southeastern sky, while on the east are Aquila, Cygnus and Lyra, with Hercules and Corona above them. Cassiopeia and Cepheus are low in the north, Draco and Ursa Minor are above the Pole, and Ursa Major is high in the northwest. Castor and Pollux are near setting in the west-northwest, and Leo is higher up in the west.

Hydra, stretching far along the southwestern horizon, brings us back to our point of departure.

The Planets.

Mercury is in conjunction with the Sun on the 17th, and is practically invisible this month.

Venus is evening star in Taurus and Gemini, setting about 8:30 P. M. on the 1st, and 9:25 on the 31st. She is in conjunction with Saturn on the 15th, the two planets being a little more than 2 deg. apart.

Mars, too, is an evening star, in Cancer, moving steadily eastward, receding from the Earth, and growing fainter, so that he seems now to be only one third as bright as Saturn. He remains in sight till after midnight, except at the end of the month.

Jupiter is a morning star in Capricornus. On the 12th he is in quadrature with the Sun, but being far south does not rise until 1 A. M.

Saturn is evening star in Taurus, setting at 8:30 P M. in the middle of the month. Uranus is in Capricornus, and comes to the meridian about 5 A. M. on the same date. Neptune is in Gemini and is observable in the early evening.

The Moon is in her first quarter at 1:29 A. M. on the 3rd, full at 4:31 P. M. on the 9th, in her last quarter at 5:12 P. M. on the 16th, and new at 9:35 P. M. on the 24th. She is nearest us on the 8th, and farthest away on the 21st. She passes near Neptune on the 1st, Mars (rather closely) on the 2nd, Uranus on the 15th, Jupiter on the 16th, Mercury on the 25th, Saturn on the 26th, and Venus on the 27th, and returns to Neptune on the 28th and Mars on the 30th.

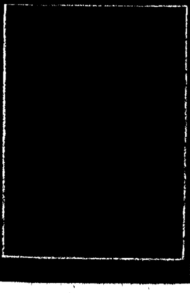
Snow plows at work in "sunny" France.

Some very severe weather was experienced in France this winter, not only in the North, but also in the South, which is noted for its mild, sunny climate The photograph depicts a very unusual scene for that region: Two locomotives with snow plows clearing the railroad at Pulchérie, near Carcassonne

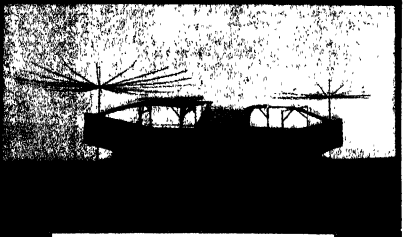
The ingenious milkman.

A dairyman in Los Angeles found it burdensome to carry the heavy cans from the milking yard to the dairy, so he rigged up the trolley system shown in the photograph, which was inexpensive and easily built. The full cans are carried on a heavy wire by a small two-wheel car, and go all the way by gravity.



A parlor car garage.

In order that he may use his motor car at any point along the line, Mr. Louis W. Hill, son of Mr. J. J. Hill, and chairman of the Board of Directors of the Great Northern Railway, has had a garage constructed in one end of his private car.



A twentieth century Noah's Ark.

Anticipating a second great flood a modern Noah is building an ark near Palo Alto, California It is to be a catamaran, which the builder plans to drive by means of four wind wheels connected to propellers. The photograph shows one of the floats. It measures 50 by 17 feet and will draw six feet of water.

ODDS AND ENDS FROM THE EDITOR'S DRAWER

New Automobile Headlight

A HEADLIGHT which differs radically from all other automobile headlights, and involves a number of exceedingly interesting new features of construction and manufacture, has been invented by Edouard Cannevel, whose "Eyeball" headlight and ingenious carbureter have already appeared in this country and have been adopted by several manufacturers of automobiles.

The new headlight embodies a peculiarly shaped reflector, which is claimed to give remarkable results with an ordinary six-candle-power lamp on an automobile. Tests with the new reflector have shown its power to be greater than that of any other reflector at present manufactured.

As will be seen from the accompanying illustrations, the reflecting device consists of a series of annular, parabolic sections in combination with a curved mirror. Light rays are thrown from the lamp sideways toward the parabolic rings and by them reflected into the mirror behind the lamp. They increase those light rays sent directly from the lamp into the mirror and into the roadway ahead. In this manner the large amount of light "lost" through uncontrolled reflection from the side walls of the headlight is utilized for roadway illumination.

In order to be able to manufacture a silvered reflector of the kind used in this headlight, the inventor had to design a special apparatus, which is shown in another illustration. It consists of an air-tight bell, from which the atmosphere is exhausted and in which a small quantity of hydrogen is liberated. Mounted upon a pivot in the center of this bell is the reflector, carrying at its upper end a magnetized bar. The reflector revolves easily between two electric poles. Revolvably suspended above the bell is a huge magnet which by its drag causes the magnetized bar inside the bell, and with it the reflector, to revolve upon its pivot. The silver to be deposited upon the reflector is volatilized by an electric current of 60,000 volts at the poles and deposited upon the glass of the reflector.

In order to protect the silver from the atmosphere and its oxidizing influence, a special protecting surface of copper is subsequently deposited upon it by means of a metal spraying process.

The Marvels of Ultra-violet Radiation

By Richard Arapu

THE English novelist, Wells, in his "War of the Worlds," describes the invasion of the earth by armless, legless, tentacled, and megalocephalic Martians, who destroy men, houses, forests, and fields by directing upon them fluorescent green rays, that ignite and consume everything that they touch.

Radiations as remarkable and almost as destructive as these imaginary Martian rays have been studied in physical laboratories in recent years These are the ultra-violet *rays*, which exist in *sunlight*, and which are produced abundantly by the quartz mercury vapor lamp.

Prof. Daniel Berthelot of the *Ecole Supérieure de Pharmacie*, who has made a profound study of these rays, said recently to the writer:

"The ultra-violet rays are the most rapid ethereal radiations that we are able to produce. This quartz lamp emits rays that vibrate 750 trillion times in a second. This prodigious number exceeds our powers of comprehension Our eyes are blind to these too rapid vibrations as our ears are deaf to sounds too high in pitch Yet, these invisible rays, which are detected by the photographic plate and perhaps by the eye of the ant, exert disastrous action on higher organisms, and especially on man"

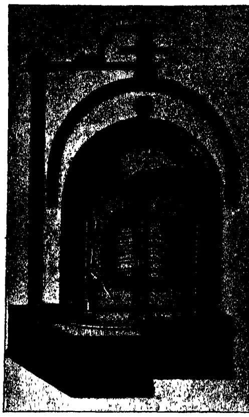
The skin exposed to ultra-violet radiation reddens, inflames and peels These are the effects of sunburn, and sunburn is explained by the abundance of ultra-violet radiations in the sun's rays

"But the eyesight is most greatly menaced by exposure to ultra-violet rays, which in a few seconds produce painful conjunctivitis and ophthalmia. An exposure of three or four minutes may cause total blindness."

This peculiar property of ultra-violet rays may be utilized in future wars. In the recent war in Thrace many nocturnal attacks were made by Bulgarian troops armed with acetylene torches, the dazzling light of which blinded the enemy and made defense impossible. The invisible ultra-violet rays can be filtered from the green light of the mercury vapor lamp by a screen of suitable material and color, and it would be easy to devise apparatus which would emit a flood of these invisible destructive rays that would actually blind the enemy.

But these rays have other wonderful properties that suggest more peaceful applications.

"The ultra-violet rays," Prof. Berthelot continued, "make foodstuffs out of the gases of the atmosphere. Under the influence of these rays carbon dioxide and water vapor combine to form sugar and other carbohydrates. Hence, it is not too rash to look forward to the synthesis of certain foodstuffs. Theoretically, we may foresee the replacement of some of our fields of grain and sugar beets by factories in which food will be produced from the atmosphere by the agency of ultra-violet rays. The engineer, the physician and the chemist will then take the place of the farmer.



Apparatus with which the new reflector is silvered.

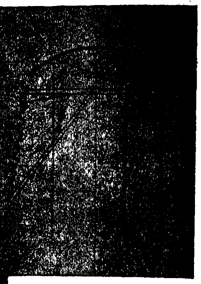


Diagram illustrating the paths of rays in ringed reflector.

"At present a kilogramme of sugar could not be produced in this way for sixty or seventy centimes. It would cost several thousand francs. But it cost Sainte-Claire Deville, the discoverer of aluminium, several hundred francs to produce a kilogramme of the metal, while pure aluminium is now worth less than two francs per kilogramme.

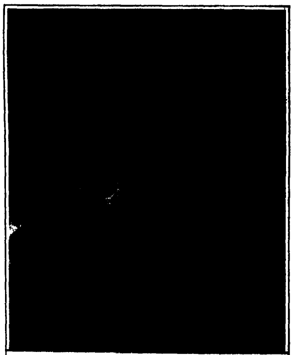
"Science moves so quickly nowadays that the partial realization of the synthesis of foodstuffs is perhaps less distant than some persons think.

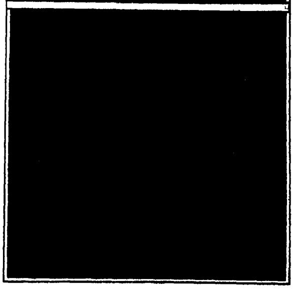
"The ultra-violet rays have also made entrance into the realm of the ferments, those mysterious leavens on which some of the oldest and most important of human industries are based. I have inclosed foodstuffs—sugar, butter, and fats—in sealed vessels of quartz, and have effected their digestion by the action of ultra-violet rays, without the aid of any ferment.

"It seems to me that I have here touched one of the mysterious secrets of life. Food is digested by the action of the saliva, the gastric and intestinal juices, etc., which contain ferments or diastases that decompose the foodstuffs into substances that the body can assimilate. I have digested artificially by the agency of ultra-violet rays, foodstuffs of the three great classes, carbohydrates, fats and albuminoids, inclosed in globes of quartz.

"Perhaps the therapy of the future will make use of internal light baths, and dyspepsia will be treated by introducing into the stomach, instead of capsules of pepsin, tiny lamps that emit ultra-violet rays."

Prof. Berthelot examining a mercury vapor lamp with uranium glass spectroscope, devised by Soret and Cornu for making ultra-violet rays visible.





Prof. Berthelot holding a Billon-Daguerre mercury vapor lamp with double walls, designed for the sterilization of water.

Protective Coatings for Objects Made of Plaster of Paris

PLASTER of Paris reproductions of famous statues can be effectively used for the adornment of pleasure grounds, porches, pergolas, etc. Unfortunately, however, they are very susceptible to the ravages of the weather. *Recettes de la Maison* (*Household Receipts*) recently published formulas for protective dressings for such objects, without, however, discriminating as to their comparative value. Whereupon a contributor to *La Nature* (Paris) undertook to make thorough tests upon this point, the results of which have just been printed. For this purpose squares of plaster, mixed and molded in the ordinary manner, were covered with various coatings and then exposed to all sorts of inclement weather. The first was treated with boiled linseed oil, the plaster being saturated by successive application of 8 or 10 layers. Under this treatment it acquired a pale brownish yellow color, and was hardened almost as much as if it had been subjected to a borax bath. A genuine but not very durable protection was afforded by this treatment, since the plaster subsequently corroded, though very slowly.

The second treatment was of wax, applied by passing a hot iron over the scrapings of wax with which the surface had been dredged. Very little of the wax is absorbed unless the plaster had been previously heated. A beautiful yellow color, slowly growing paler, was obtained and the subsequent exposure left the plaster absolutely unaltered. The third application was of paraffine, which can be applied in two ways. First in the melted state, spread by hot iron, and secondly dissolved in carbon disulphide. This solution better penetrates the thickness of the plaster. In each case the plaster becomes a pale gray in color and the hardness is not modified. Both methods afford very efficient protection. The fourth material used was stearine, scrapings of candle-ends being spread over the surface by a hot iron. The result was a crystalline coating changing the white to pale gray. The protection furnished was excellent.

Finally, a 10 per cent solution of gelatine was used. The plaster absorbs little, because gelatification occurs soon after deposition. Parts of the surface were subsequently coated respectively with alum, bichromate of potash, and formol. In no case was this treatment successful, since the gelatine layer always dissolved or scaled away.

The conclusion drawn, therefore, is that wax, stearine, and paraffine are the best preservatives, and since the last is the cheapest it is probably best for most cases. It may be applied either by heating the surface or dipping the object in a hot bath of the melted substance used.

A Memorial to Benjamin Franklin is to be erected in what is probably the most interesting old church in England, viz., St. Bartholomew the Great, in Smithfield. Franklin worked as a printer in this church, part of which was then devoted to secular uses.

Exploding Mines by Wireless Telegraphy

By Dr. Charles Forbes, Columbia University, New York

THE newspaper accounts that have appeared from time to time in regard to the explosion of submarine mines by means of radio-telegraphy might lead the ordinary reader to believe there is danger of exploding powder magazines on war vessels, and torpedoes and mines located in harbors for defense, in the daily use of the wireless telegraph. Such an event cannot, however, take place without the intervention of apparatus specially constructed for the purpose.

An interesting laboratory experiment illustrative of the subject may be performed as follows: There must be apparatus for generating the electric waves, known as the Hertzian, from their discoverer; also apparatus for receiving the impressions produced by them. Like the telegraph and telephone the transmitting and the receiving instruments are essential. For the laboratory experiment the transmitting apparatus may consist of the usual amateur outfit. In the absence of this the sparks from an influence electrical machine, the induction coil or the Leyden jar will be sufficient to set up the Hertzian waves. In the simplest form the Leyden jar answers the purpose very well. The receiving apparatus consists of the Branly coherer, which is placed in series with a suitable electric battery, two dry cells being sufficient, and a relay, which in action closes a second electric circuit generated by another battery of two dry cells. This current is conducted by communicating wires to the exploding fuse in the mine to be exploded.

Inspection of the illustration will show the wiring and the arrangement of the apparatus for the laboratory experiment. Fig. 1 represents the Leyden jar being discharged by the discharging rods. Electric waves are represented passing outward in all directions ready to impinge upon receiving apparatus situated in their path. Fig. 2 represents the receiving apparatus. The coherer is at *A*, the battery at *B*, the relay at *C*, the relay battery at *D*, and the mine to be exploded at *E*, resting in a tank of water.

On discharging the Leyden jar, this is what takes place: The electric waves thereby generated pass onward through space, and acting on the coherer, its battery is set in operation, thereby closing the relay circuit, which in turn actuates the fuse, when the explosion of the mine is effected.

The essential part of the receiving apparatus is the coherer. The details of its construction are represented in Fig. 3. A glass tube about 2 inches in length is represented at *F*. Into this there are fitted rather snugly, brass or copper rods *G*; the internal ends being separated about one eighth of an inch and the external ends having metal disks attached, somewhat larger than those represented in Fig. 2. The space between the internal ends of the rods is to be nearly filled with filings of nickel about 9 parts and silver 1 part. If the pure metals are not available for the filings nickel and silver coins may be substituted. A trace of mercury, which is desirable, may be secured by amalgamating the internal ends of the rods in the glass tube. The coherer has this peculiar property; the filings, in the inactive condition, offer a high resistance to the passage of a battery current of electricity; when acted upon by the electric waves they are said to cohere, offering much less resistance, thereby allowing a much greater electric current to pass. This is sufficient to actuate the relay.

The miniature mine to be exploded is represented in Fig. 4, about the actual size. It consists of a metal tube with a rubber stopper inserted at its upper end and another at the lower end. Through the lower stopper the insulated conducting wires from the relay battery pass. The terminals are connected by a fine iron or platinum wire, which is imbedded in the gun powder in the inclosed chamber. The fine wire on becoming incandescent ignites the powder and the explosion takes place. Interest will be added to the experiment if, preceding the explosion of the miniature mine, the closure of the relay current be made to ring an electric door bell, and if by tapping the coherer, the ringing may be discontinued. In a similar manner electric lights may be lighted on substituting the electric light current for the relay battery current. In actual practice the sending apparatus of the wireless telegraph would be used to set the ether waves in motion and the submarine mine would be attached directly or indirectly to the receiving apparatus. From the above described experiment, it is quite evident that the accidental explosion of mines and other magazines of explosives by means of the Hertzian waves is very improbable. An explosion by electrical induction would be a very different thing, and could only take place at a distance of a few feet. For its occurrence, specially arranged apparatus would also be necessary.

A New Experiment to Determine the Earth's Rigidity

A NEW and improved method for determining the rigidity of the earth has recently been devised by Prof. A. A. Michelson, director of the Ryerson Physical Laboratory of the University of Chicago.

The method consists essentially in measuring with great accuracy the tides in two steel tubes half filled with water. The tubes used in this experiment are of steel, each 500 feet in length, lying horizontally upon solid concrete foundations in trenches six feet deep, and are carefully insulated against temperature changes and other outside disturbances. They are placed at right angles to each other, the one in a north-south direction and the other in an east and west line The water in the tubes communicates with chambers at the ends, where, by an ingenious arrangement, the change in level, i. e., the deviation from the true level due to tidal action, can be measured to a ten thousandth of an inch.

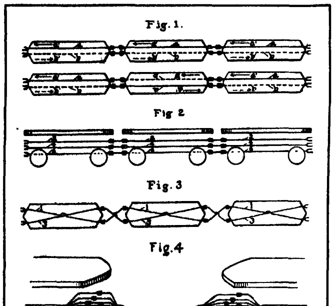
The object of thus producing tides in a closed tube is to eliminate as far as possible the unknown factors that play a part in natural tides, such as contours of coast-line, wind, ocean-currents, meteorological conditions, etc. The tide in these tubes is the resultant of two main factors; the deformation of the earth due to the attraction of the moon and the tractive force exerted by the moon on the water directly. This latter force can be calculated mathematically, and by subtracting this calculated amount from the tide actually observed the component due to the earth's distortion is found. Knowing the force exerted by the moon on the earth, and the amount of deformation produced by this force, the rigidity of the earth can be calculated.

The actual computations are far from simple, however, as the forces exerted by all the larger planets must be considered and various complicated correction factors must be introduced.

Arrangement of Wires in Multiple-unit Trains

By Samuel W. Balch

THERE are a number of pretty geometrical problems in the arrangement of the train signal wires which run through the multiple-unit trains for controlling the operation of the electric motors on the different cars. In order to understand the arrangement, it will be sufficient to assume that the motors and their controllers have seven speed arrangements, each of which can be brought about by turning current into the corresponding speed-signal wire, and the motor arrangements will be made the same on all the cars. In addition there are two direction positions which require two additional wires.



How the signal wires for controlling the motors of multiple-unit trains are arranged.

In the multiple-unit system these positions are selected by nine signal wires running through each car and coupled together where the *car platforms meet*. They are connected on each car to magnets, which need not be described here, so that if one of the speed wires and one of the reverser wires have current turned into them the same driving conditions will be set up on all the cars A peculiar difficulty arises first from the fact that the direction in which a car will run with a given position of its reverser is a direction with respect to the car itself and not with respect to the points of the compass, Thus, if a car were taken from the main track on a Y switch and returned on the other branch of the Y, it would be turned around and the position of the reverser, which originally stood for north movement, would now stand for south movement To prevent a car which has thus become turned end for end in a train from being at cross purposes with the other cars, the signal wires have simply to be run through the train parallel and in the same horizontal plane

In Fig 1 two trains are shown with the reversing signaling wires In the second train the middle car is turned end for end. Turning current into signal wires *a a* sets the reversers on all the cars to run in the directions shown by the arrows *a' a'*, and turning into the signal wires *b b* sets the reversers oppositely. When the middle car is turned end for end and the wire *a* is given current at the head car, the wire *b* receives the current on the middle car and returns it to wire *a* on the rear car Simple as this arrangement is, several of the first inventors of train lines do not show it in their patents.

The speed controlling wires require to be connected, wire 1 to wire 1, wire 2 to wire 2, and so forth, no matter how the cars are brought together into a train in whatever end to end relation or order There are two ways of insuring this One way is to put them on different levels and in the same vertical plane as shown in Fig. 2. Another is to leave them on the same level as in the case of the reverser wires, but the train wires must be crossed as shown in Fig. 3 The connections however must be crossed back again in the jumpers between cars If only the wires through the cars were crossed, connections would still be kept right in case a car should be turned end for end, but wires 1 and 3 would be in exchanged positions in the odd positioned cars of the train as compared with the even positioned cars of the train, and a car wired for position 1, 3 or 5 could not be used in position 2, 4 or 6. The difficulty is overcome by the crossings in the jumpers These are in effect extra sections of the train line so that the train line sections on the cars are only the odd numbered sections. The detachable sections between cars are necessary in the form of the flexible jumpers as shown in Fig. 4 to conform to the flexibility of the train. Each set of terminals is brought together in a head so that the coupling of all can be performed at one operation, and the three systems described are combined to secure a compact arrangement of the nine terminals. This arrangement at one end of a car or jumper is as in Fig 5, and at the other end as in Fig. 6

As in practice there is no room for the coupling at the center line of the train, the couplings are repeated on both sides, either of which is coupled according to convenience. The wires, however, can have the same arrangement as for the center line, and this plan is followed in all multiple-unit installations

Where two train lines thus become necessary, a simpler solution is possible, in which all the wires are run parallel in each train line, but in right and left arrangement in the two lines. This was the case in the first multiple-unit installations by Frank J Sprague, but it was not known to the engineers who developed the system at present in use. Other ways of doing this are shown in patents No 405,897, June 25th, 1889, Harry W. Leonard; No. 660,065, October 16th, 1900, Frank J. Sprague.

Who Will Imitate Jeffery Next Year?

Wide public endorsement has been given to the idea which Jeffery brought over from Europe last fall—the high speed, light weight, economical, four cylinder motor. He it was who first put this dominant idea into American practice—produced the first light weight economical, high grade Four to sell at $1550.

There are persistent reports that other makers will pay tribute to Jeffery by producing cars of a similar type—next year. Imitation is, indeed, the most sincere flattery and we welcome this imitation with hearty good will.

The unmistakable demand for light weight and economy has become so pronounced that engineers do not hesitate to publicly endorse the idea which has made the Jeffery a big success.

It is well known that the biggest successes of the industry have been founded upon cars of this type. Yet, during the past two years, the tendency towards heavy weight in design became so pronounced that people who valued economy, light weight and low upkeep expense were forced to buy low priced cars.

For two years there was little improvement in the design of motor cars except in body details and such features as starting devices. Then a great wave of economy spread over the country. People were forced to take inferior quality, scant comfort and sacrifice appearance to realize economy.

Jeffery saw that the industry was traveling in the wrong direction. He sent his engineers to Europe, where the best makers have already had the same experience which most American makers must yet go through. The high speed motor is dominant over there—it has made good. Jeffery brought that idea to America. Then he built the Jeffery Four at $1550 and the Jeffery Six at $2250. Power he attained through speed instead of bulk.

In five months orders have been taken for seven thousand Jeffery cars.

Now the light, economical car has won the victory. The big sale of Jeffery cars is evidence enough of that. Our shipments during the first three months of the year exceeded those of last year by 103 per cent.

Read the clipping from Motor Age opposite and you have concrete evidence of what will certainly be the dominant type in years to come.

The Jeffery Four represents that dominant type.

The leading trade papers are commenting every day upon the superiority of the small, high speed motor. Jeffery introduced that type into America last fall.

It is quite likely that other light Fours will be built, but we do not fear this competition because there is embodied in the Jeffery Four the best material that the market affords and the best ideas developed by the best mechanics in the world.

Fortunately, Jeffery is in the best position to meet the keenest competition. He has no stockholders to satisfy. He is the one man in the United States who controls a complete automobile factory and every dollar's worth of equipment is paid for. He discounts all bills. Therefore, he is able to buy right. He is satisfied with a small profit. Therefore, he can build the best four cylinder car in America and sell it at a price which cannot be duplicated by manufacturers lacking his capital, equipment and experience.

Here are the specifications which gave Jeffery leadership in sales after he attained leadership in ideas.

SMALL HIGH SPEED MOTOR, introduced by Jeffery November, 1913.

IMPORTED ANNULAR BALL BEARINGS—endorsed by cars selling above $4,000—adopted by Jeffery.

RAYFIELD CARBURETOR—endorsed by dealers—adopted by Jeffery.

VANADIUM STEEL SPRINGS AND AXLES—endorsed by everybody—adopted by Jeffery.

FOUR SPEED TRANSMISSION—demanded by the public—adopted by Jeffery.

MOST EXPENSIVE FULL FLOATING REAR AXLE—most costly—most quiet starting and lighting system—most expensive body in design and finish—Spicer universals—the last word with mechanics—pressure feed gasoline tank—Neverleek top—oiling system best known—Bosch Duplex ignition—left steer and center control—cone clutch—wheel base 116 inches—demountable rims—equipment—top made of best material, top cover, rain vision windshield, robe rail and foot rest—Klaxet horn, Solar electric lamps, power tire pump and complete tool equipment.

Electric lighted auxiliary dash, on which is mounted Warner autometer, ammeter, gasoline and oil pressure gauges, light switch, coil switch, electric horn button and two compartments for valuables. The one electric light switch has four positions to operate—the side, head, dash and tail lights. Switch can be locked in any position. Tail light and dash light work on relay.

THE WISE BUYER WILL GET A JEFFERY FOUR, now because next year his car will still embody all the leading construction principles. It is made from the best materials that can be put into any car at any price. Find the nearest Jeffery dealer today.

RECENTLY PATENTED INVENTIONS

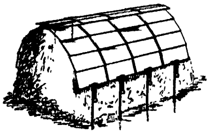
These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the SCIENTIFIC AMERICAN.

Pertaining to Apparel.

HAT BRIM PRESS.—F. HUSS, 68 Wooster St., New York, N. Y. This invention provides means for stretching the brim while in the press and under control; and provides power means manually operable for exerting an extra pressure upon the material forming the brim, said means being controllable to conform to the inherent conditions of various materials.

Of Interest to Farmers.

HAYSTACK COVER.—F. A. FREELAND, Athelstan, Iowa. This invention has special reference to novel and useful improvements in covers for haystacks The primary object of the invention resides in the provision of an improved cover which will automatically adjust itself to a stack as the latter settles, whereby the stack will not only be protected, but the cover will be prevented from blowing loose in case of high winds The accompanying illustration is a perspective view of the improved self-adjusting haystack cover applied to a stack.



HAYSTACK COVER.

SWEEP RAKE.—W. H. SELLERS, JR., Florence, Kan. The purpose of the invention is to provide the teeth of the sweep rake with means whereby the hay may be sufficiently compressed and packed on the stacker as to prevent it from falling away with the sweep rake when the latter is withdrawn.

COTTON PRESS.—J. H. BODDIE, 802 S. 6th St., Muskogee, Okla. An object here is to provide a dog locking and releasing means for the revolving press boxes whereby the cotton after compression by the tramper is held during the revolving of the box from its receiving position under the tramper to its transfer position under the ram and under the compressing and baling box. At this point the dogs are automatically released so as to allow the ram to raise the partially compressed cotton in the compressing and baling box.

AUTOMATIC HAY-EJECTOR FOR SWEEP RAKES.—B. F. LEWIS and J W LEWIS, Hartland, Kan. Address E. R. Shorpe, Larkin, Kan The present invention is an improvement on the patent granted to these inventors, No. 1,038,168 In the latter the hay ejector or hay pusher is required to be adjusted manually by the driver of the rake in order to throw it into and out of action, whereas in the present, the action is entirely automatic, thus effecting a considerable saving in time and expense.

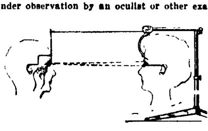
ROPE TAKE UP.—J. C. WILLIAMSON, Cordele, Ga This device is for use in stump pullers and like machines, wherein a take-up or tie is provided for connecting the stump to the pull rope, so arranged that after the stump has been pulled, the take up or tie may be released from the pull rope, and removed to another stump, and without interfering with the operation of the pull rope as it pulls the succeeding stump

WEED PULLER.—D GOTTFRIED, Quindan Station, Kansas City, Kan This device is capable of being held in the hand, and has means for grasping and holding the weeds so arranged that the weeds may be grasped lengthwise of the stalk and beneath the surface of the ground if desired

STEERING DEVICE FOR CULTIVATORS.—A T HOLMES, St. John, Wash The more particular purpose of the invention is to enable the operator to cause the cultivator to make a comparatively short turn, thus occupying a minimum of room for the purpose and also enabling the turning movement to be easily executed.

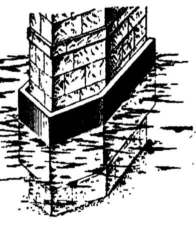
Of General Interest.

OPTICAL INSTRUMENT.—W WORK, care of Herman S. Hewett, 110 Main St., Brockton, Mass This instrument is for use in conjunction with a plano retinoscope, arranged to permit of quickly and accurately determining the amount of refraction of the eye of a patient under observation by an oculist or other examiner, to insure fitting the patient with eyeglasses or spectacles having correct spherical, cylindrical or compound lenses. To accomplish the desired result use is made of an indicator and controlled by the examiner during the use of the plano-retinoscope.



OPTICAL INSTRUMENT.

PIER PROTECTOR.—S. C. MAY, 880 Tenth St., Modesto, Cal. Means in this invention provides protection for bridges, piers or the like from damage due to floating logs, ice or débris carried by currents of water. Among the objects, therefore, of this inventor is to provide a means of a simple and permanent nature adapted to be secured to or arranged in association with a pier or the like projecting into or upwardly from a body of water, said device being so arranged with respect to the pier as to float upon the surface of the water whereby it will always be automatically maintained at proper elevation with respect to said surface.



PIER PROTECTOR.

SHAVING AND LATHER BRUSH.—D. I. HARTMANN, 137 Regent Place, Brooklyn, N. Y. This invention includes a handle, a set of bristles and a massager carried by the handle and located within the mass of bristles,, the arrangement being such that the bristles may be used as usual for the application of soap to the beard and then for the massager to be brought into use by a slightly greater pressure upon the handle for the purpose of forming the lather directly upon the face without the operation of the fingers.

BEARING.—C. G. LUNDGREN, 210 Adams St., Chicago, Ill The purpose here is to provide a bearing which may be used on grinding wheel heads, and to provide solid tapering bearing members, which are adjustably secured to the heads, so that they may be moved longitudinally when slightly worn, to fit snugly the tapering portion of the spindle carrying the grinding wheel

LOOSE LEAF BINDER.—W. C. TRAHER, London, Ontario, Canada. The covers are manufactured rapidly and complete before the locking hooks are secured in place. They may be passed through rollers in the last stages of manufacture, which could not be done if the hooks were secured to the covers before the latter were completed. Plates for the hooks are corrugated, which permits of the use of very cheap metal, wires being provided, the central portions of which are clamped by the plates with wire terminals bent to form hooks. Each corrugated plate has bent spring flanges, which engage the companion plates for holding the plates in position when their outer edges are slid within the flanges of the spring plate which is secured to the covers after their completion.

COMBINATION REINFORCING ROD AND WALL PLUG.—J MCLOUGHLIN, Glen Cove, N. Y. This invention relates to devices used for supporting the molding board or planking of any kind on a brick or concrete wall; and has reference more particularly to a device comprising wooden wedges at a predetermined distance from one another, having an edge flush with the wall incorporating the same.

CABLE GUIDE.—H. HOLMES, Noyo, Cal. In the present patent the invention has for its object the provision of a cable guide inexpensive to manufacture and one having a free movement for use in directing the cable as may be desired and under all conditions of operation.

LUMBER JACK.—C. E. EVANS, Weed, Cal. The jack has a yoke with a stud journaled in a supporting arm, and studs carry a member having teeth for engaging the lumber. The teeth are inclined to adjust the yoke relatively to the supporting arm to hold the yoke so that the teeth will be inclined as desired relatively to the supporting arm. Pins extend from the teeth member to limit the latter's movement. A collar is held in adjusted position relatively to the stud by a cotter pin, this collar being provided with a flange for engaging the supporting arm to check the rotary movement of the yoke relatively thereto.

HORSE OVERSHOE.—C. E. DEUSCHER, 228 St Ann's Ave., Bronx, N. Y., N. Y. This device is adapted to be easily attached to or removed from the hoof, and is provided with gripping devices of peculiar construction adapting them in a superior degree to the making of a sure hold upon the ice, and may be readily replaced if worn out or broken.

MUSIC HOLDER.—E. J. BABBITT, Onaway, Mich. This holder comprises a base and a music supporting frame provided with means for engaging beneath the front board of a piano, the base and the frame slidably and frictionally connected to permit relative adjustment of the frame when the base is in engagement with a fixed support, and of the base when the frame is engaged with a piano.

GREASE CUP.—E. H. [illegible], 1777 Broadway, New York, N. Y. The improvement provides a base adapted to be secured adjacent a bearing, said base having a delivery tube, and means for quickly attaching thereto a cup filled with grease, special means being provided to prevent a loss of said cup from the base or any tendency for the parts to rattle when in use.

MOTOR.—B. STEWART and D. B. STEWART, Garden City, Kan. This water motor is adapted to be arranged in a flowing stream, and is provided with vanes for engagement by the water to rotate the wheel, so arranged that on one side of the wheel the said vanes will automatically take a position at approximately right angles to direction of the flow, and on the other side will automatically take a position approximately parallel with the direction of flow to offer the slightest possible amount of resistance to said flow.

DETACHABLE HORSESHOE CALK.—G. I. DE FORCE, Erie, Pa. This calk is one which is capable of quick attachment and detachment, which may be attached without loosening or removing the shoe, which will not engage the hoof of the horse nor incommode the horse in any way, which will fit any shape hoof, and which is so arranged that the greater the strain the more tightly the device grips the shoe.

Hardware and Tools.

KNIFE AND SCISSORS SHARPENER.—A. HELMER, 826 53rd St., Brooklyn, N. Y. This inventor provides a device designed to be adjusted so that either a knife or pair of scissors may be sharpened by an unskilled person. It provides a pair of abrading rollers and means for locking the same in adjusted position, together with means for guiding the blades of a pair of scissors against one of the rollers.

SAW JOINTER.—WILLIAM E. GIBBS, care of W. L. T. Co, Oak Point, Wash. The device of this patent provides a novel arrangement of adjustable members and gage elements designed to provide a simple construction permitting of a wide range of adjustments to adapt the tool to the various operations of jointing, filing, and swaging, and enable the same to be performed with facility and accuracy.

COMBINATION TOOL.—L. KALINA, 132 Nassau St., New York, N. Y. The inventor provides a combination tool embracing a key ring, scissors, button hook, cigar cutter, and bottle opener, and arranged to take up very little space when the several devices are in folded position, thus allowing of conveniently carrying the combination tool in a vest pocket.

TOOL.—J. E. W. BOSSCH, care of Overbeck Bros., Columbus Ave. and 82nd St., New York, N. Y. The invention provides a tool having a pivotally mounted member on the end, and a reciprocating or removable hammer structure for locking the pivotally mounted portion of the tool in various adjusted positions so as to cause the same to act as a hammer, a wedge, tack puller, box opener, etc.

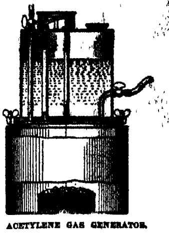
ASSEMBLING SOLDERING TOOL.—J. E. EBAUGH, 215½ W. Reed St., Moberley, Mo. This tool is especially adapted for holding two parts in assembled relation so as to be soldered or otherwise united, the tools being in the nature of pliers designed for use by jewelers, opticians and the like for conveniently holding broken parts together while being soldered.

Heating and Lighting.

SUPERHEATER.—E. J. AKINS, Moundsville, W. Va. The invention provides a device for utilising the waste heat from a traction engine or similar machine, for superheating the exhaust steam and again utilising the same in any desired manner, as for instance in a low-pressure cylinder.

SECTIONAL STEERING WHEEL.—L. E. LAURANCE, Stites, Idaho. This invention is in sectional steering wheels, and like hollow bodies, and provides a hollow body consisting of separable sections and having partitions separating the interior of the hollow body into compartments, sundry of these having openings covered with transparent coverings, the hollow bodies being adapted to contain heating and illuminating devices for heating the hollow body and for illuminating objects near the said body.

ACETYLENE GAS GENERATOR.—E. W. HOLLINGSWORTH, Columbia, S. C. The carbid is first put in and the tank secured to a casing by bolts. Water is introduced into the tank through an opening, after which the screw cap is placed in position. As water flows through the openings it drops down upon the carbid and acetylene gas is generated. As the water flows into the casing, air is drawn through an opening to take the place of the water. As gas pressure rises it forces the piston upwardly, thereby causing a needle valve to shut off the flow of water through the medium of a lever. The gas is used by connecting the feeding device with a stop cock. By connecting to the stop cock part of the gas may be used for lighting purposes. Pressure decreasing sufficiently within a [illegible] the needle valve to again permit water to [illegible] access to the carbid and the gas will [illegible] to generate again. Thus, action of the generator is automatic.

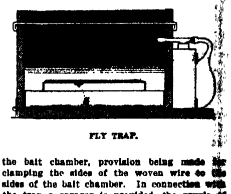


ACETYLENE GAS GENERATOR.

Household Utilities.

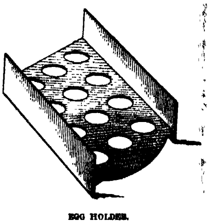
TOWEL HOLDER.—J. E. ADAMS, Box [illegible], Loveland, Ohio. This improvement relates to a towel roller, and particularly to a roller having a novel means for securing the same at one end to a suitable support, there being a novel arrangement of bearings for a [illegible] center rod on which the roller revolves.

FLY TRAP.—C. H. CURTIS, Bluffton, [illegible]. In carrying out the invention a trap chamber is formed of woven wire or equivalent [illegible] or openwork material, and is arranged above the bait chamber, provision being made for clamping the sides of the woven wire to the sides of the bait chamber. In connection with the trap a sprayer is provided, the nozzle of which is so arranged that a spray of insecticide to destroy the flies may be directed into the trap chamber.



FLY TRAP.

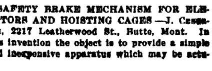
EGG HOLDER.—C. S. WEBER, 10 De[illegible] St., New York, N. Y. This holder stores eggs in ice boxes, provision chests, in pantry shelves, and the like, and is arranged to safely hold a dozen or more eggs in a comparatively small space, to allow of conveniently placing the holder with the eggs thereon into a household receptacle or onto a shelf and to protect the eggs against injury by other articles when placing the latter into an ice box or removing the same therefrom.



EGG HOLDER.

Machines and Mechanical Devices.

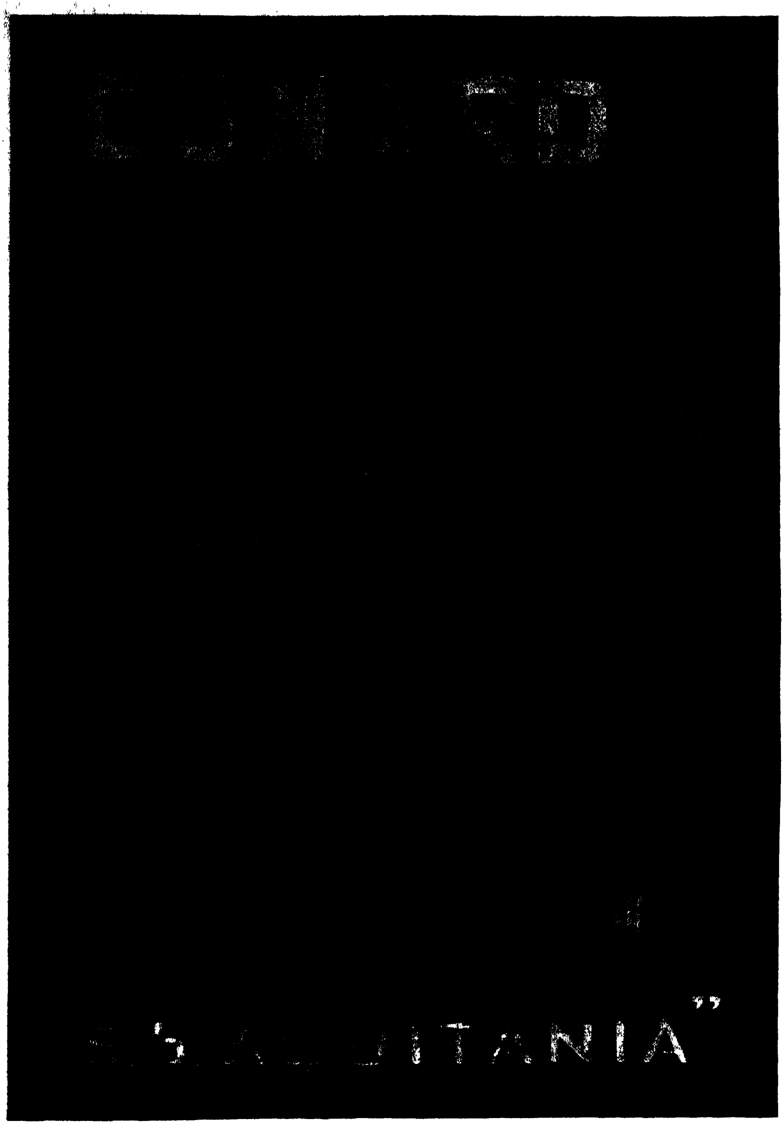
SAFETY BRAKE MECHANISM FOR ELEVATORS AND HOISTING CAGES.—J. C[illegible]ANI, 2217 Leatherwood St., Butte, Mont. In this invention the object is to provide a simple and inexpensive apparatus which may be actuated by a passenger or other person on the cage, in case of an accident such as the breaking of a rope, engine running away, a wrecked shaft; and other causes, permitting the passenger or other occupant of the cage to quickly and effectively check the lock and cage against movement.



SAFETY BRAKE MECHANISM FOR ELEVATORS AND HOISTING CAGES.

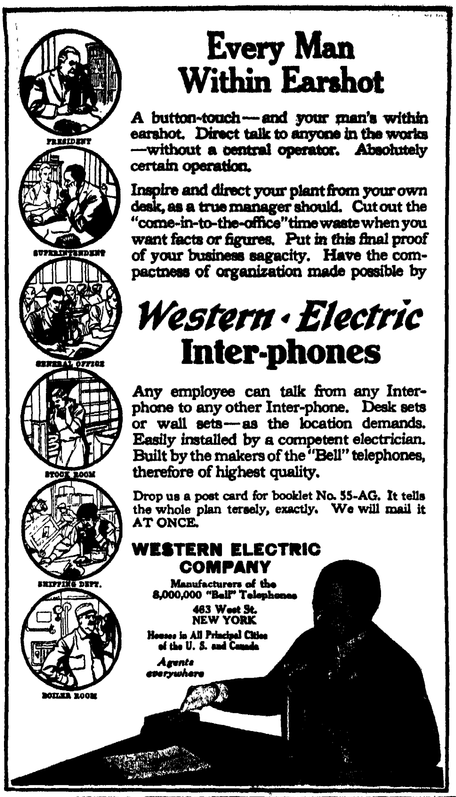
SUBMARINE MINE.—GIOVANNI E. [illegible], Rome, Italy. This invention relates to an ad-

(Continued on page [illegible].)



The first modern trans-Atlantic steamship, the "Britannia," was built in 1840 by the Cunard Steamship Company. She was unsurpassed in *her* day.
The latest modern trans-Atlantic steamer is the "Aquitania" of the Cunard Steamship Company. She is unsurpassed in *our* day.
Seventy-five years of Cunard experience in attaining supreme stability, speed and comfort are embodied in the "Aquitania."

Sailing from New York, June 10th, July 1st, July 22nd, August 26th



Every Man Within Earshot

A button-touch—and your man's within earshot. Direct talk to anyone in the works—without a central operator. Absolutely certain operation.

Inspire and direct your plant from your own desk, as a true manager should. Cut out the "come-in-to-the-office" time waste when you want facts or figures. Put in this final proof of your business sagacity. Have the compactness of organization made possible by

Western-Electric Inter-phones

Any employee can talk from any Inter-phone to any other Inter-phone. Desk sets or wall sets—as the location demands. Easily installed by a competent electrician. Built by the makers of the "Bell" telephones, therefore of highest quality.

Drop us a post card for booklet No. 55-AG. It tells the whole plan tersely, exactly. We will mail it AT ONCE.

Notes for Inventors

A Novel Target.—In a patent No. 1,092,425 Frederick Bohn of Kiel, Germany, describes a target for marine aiming drill. The target simulates the movement of a rolling ship, being for such purpose given a movement, with alternate velocity, up and down and laterally.

Improved Refrigerating Apparatus.—Adolphe E. Bossé of Pittsburgh, Pa., has secured patent No. 1,092,426 for a refrigerating apparatus by which to prevent the improper operation of the apparatus and thus avoid accumulations of high pressure of the gas.

Typewriter Eraser Operated by a Key.—In patent No. 1,083,466 Harry I. Seddon of Portland, Ore., provides an erasing means for a typewriter in which an erasing head is yieldingly pivoted on a bar and the latter is connected to a key lever so that the key lever may be moved to operate the eraser.

French Artificial Wood.—Information has been made public in Lyons, France, concerning an artificial wood, which, it is stated, will be of great value as a substitute for natural wood. The new product has been found after years of study and practical experiments, the most recent of which have given eminently satisfactory results. The process consists in transforming straw into a solid material having the resistance of oak. The straw after being cut into small pieces is reduced to a paste by boiling, to which certain chemicals are added. When the paste has been reduced to a homogeneous mass it is put into presses, and planks, beams, laths, and moldings of all sizes are readily made. This new material can be sawed like natural wood. As a fuel, it emits a bright flame and little smoke. It is further stated to be adaptable to the manufacture of match stems.

An Automatic Gas Extinguisher.—Edwin H. Hawley of Washington, D. C., in patent No. 1,088,987 shows an automatic gas extinguisher in which a self-closing stopcock is released by a trigger arranged adjacent to a flexible diaphragm carried by an annual air chamber made of thin sheet metal and located above the burner, the trigger being adapted to release the self-closing stopcock.

A Dose-indicating Glass Cover.—Ithamar P. Berthrong of Washington, D. C., has secured patent No. 1,091,114 for a dose indicator. A glass cover has a central depression to receive a spoon bowl. An upstanding rim flange is notched to receive the spoon handle and is provided with dial fingers corresponding with the notches, so that the location of the spoon may indicate the time when the next dose should be taken.

An Illuminated Practice Target.—In patent No. 1,091,116 to William H. Buel of New Haven, assignor to Winchester Repeating Arms Company, is shown a target whose impacted surface is prepared with a flash-light composition ignited by the impact of a bullet so that a circumscribed area about the point of strike is illuminated, and can be seen by the marksman.

Sterilizing Liquid by Means of Ultra-Violet Rays.—Patent No. 1,091,221 to the R. U. V. Company, Inc., of New York, presents an apparatus for sterilizing liquid in which a vapor electric lamp is immersed in the liquid in a tank and an envelope permeable to ultra-violet rays surrounds the part of the lamp which emits ultra-violet rays, air being exhausted from the intermediate space.

Printing Signs on the Pavement.—William J. Ryan of Sapulpa, Okla., in patent No. 1,092,749 provides means for stamping a sign or advertisement on a street pavement rapidly and at successive intervals.

Helping the Eye to Follow a Golf Ball.—William Hiram Brown of Cleveland, Ohio, in patent No. 1,091,186 provides a device designed to aid in teaching a golf player how to make a stroke, it being based on the idea that a golf player shall "keep his eye on the ball."

A Novel Air Brake System.—Frank H. Dukesmith of Meadville, Pa., assignor to Thomas C. Vanhorne, Pittsburgh, Pa.,

LEGAL NOTICES

PATENTS
Trade Marks Designs Copyrights &c.

INVENTORS are invited to communicate with Munn & Co., 361 Broadway, New York, or 625 F Street, Washington, D. C., in regard to securing valid patent protection for their Inventions. Trade-Marks and Copyrights registered. Design Patents and Foreign Patents secured.

A Free Opinion as to the probable patentability of an invention will be readily given to any inventor furnishing us with a model or sketch and a brief description of the device in question. All communications are strictly confidential. Our Hand-Book on Patents will be sent free on request.

Ours is the Oldest agency for securing patents; it was established over sixty-five years ago.

All patents secured through us are described without cost to patentee in the Scientific American.

WAN ENGINE OF 3, 5, or 7 CYLINDERS or more, with a rotary valve, that can be used for [illegible] ing purposes or ship steering, or for any other purpose where reversible power is needed—can be reversed instantly under full pressure—working with gasoline or steam. Simple, and cheap to make. Address H. B. Ogden, 204 Carroll St., Brooklyn, N. Y.

FOR SALE. PATENT JUST ALLOWED. Door Check and Closer. Low cost to manufacture. Demand already created. Send for information regarding sale or royalty. John A. Cross, Westwood, N. J.

DISPLAY LAUNDRY RACK FOR HOUSEhold starch clothes. Will sell Canada or U. S. outright or royalty. For further particulars address F. R. Holland, 18 Atlantic St., Maspeth, L. I.

PAT. No. 1,088,882, improvements in Steam [illegible] very effective—practical—simple and cheap to build. Patent for sale reasonable. Address owner, Lam[illegible] Coster, 317 16th Street, College Point, N. Y.

SCIENTIFIC APPARATUS

GLASS APPARATUS, thermometers for scientific and industrial laboratories, surgical glassware, experimental work. For further particulars address Laboratory Supply Co., 128 State St., Rochester, N. Y.

VALVE CLEANER

FORD OWNERS. Wall's Ford Valve Cleaner will clean carbon from valve seats without removing cylinder heads. Automatic rotating motion. Easy to operate. $2.00 delivered. Send for circular. J. [illegible] Wall, Bristol, R. I.

INQUIRIES

Inquiry No. 9364. Wanted the name and address of buyer of mica in a crude state.

Inquiry No. 9365. Wanted the name and address of a manufacturer of machinery for embossing the foil as is used in packing cigarettes.

Inquiry No. 9366. Wanted the name and address of a manufacturer of wire wheels, front axles complete with steering or separate, light sheet metal bodies, fuel tanks with cocks, pressed steel frames, mufflers, motors of the two cylinder opposed type, cushions and many smaller parts for cycle cars.

Inquiry No. 9367. Wanted the name and address of a manufacturer of an automatic centering machine.

Inquiry No. 9368. Wanted, the name and address of glass-bottle manufacturers or glass blowers who can manufacture a glass bottle and perforate it with some 12 small holes, in large quantities for export, to sell at a popular price.

Inquiry No. 9369. Wanted, the names and addresses of users of Indian Steatite (Soapstone), Corundum and other Indian minerals, in quantities.

Inquiry No. 9370. Wanted the names and addresses of manufacturers of small wooden articles, particularly in such soft woods as pine and fir, for articles such as toys, furniture, etc.

Inquiry No. 9371. Information wanted where one could buy or have made to order machine to be used for making solid back brushes.

Inquiry No. 9372. Wanted the name and address of manufacturers of a collapsible box about 12 inches square. It must be strongly made to withstand rough usage in transit.

LEARN WATCHMAKING and become independent. [illegible] Good-Paying Positions Secured. [illegible] ways in demand. Easy to learn [illegible] while studying. Write for [illegible] St. Louis Watchmaking School, [illegible]

[illegible] for an air [illegible] for holding [illegible] the train [illegible] pulling the train [illegible]. The engine brake is also held while [illegible] the train auxiliary [illegible], and the engine brakes are set without setting the train brakes.

Economical Firing of Locomotives.—George C. Weston of St. Louis, Mo., in patent No. 1,092,466 records the number of times the locomotive fire door is opened and aims thereby to induce the fireman to fire in a more economical manner by keeping the fire door closed as much as possible.

Safeguarding the Operator of Power Presses.—Milton E. Winans of Newark, N. J., assignor to Western Electric Company of New York city, in patent No. 1,092,667 guards against injury to the operator of a power press. When the treadle or supporting device is inadvertently held or depressed in abnormal position the machine cannot repeat its operation or stroke to the injury of the operator.

Folding the Gas Stove Into a Wall Recess.—Patent No. 1,092,681 to Raymond Stuart Way of Los Angeles, Cal., assignor of one half to Charles W. Prestley of same place, by a novel construction permits the folding of a gas stove out of the way into a recess in the wall when not in use.

Paper Feeding Apparatus.—In patent No. 1,092,437 Milford B. Ferguson of New York city, assignor to Package Machinery Company of Massachusetts, shows a paper feeding apparatus especially designed to feed single sheets from a stack in such manner as to overcome the liability of the apparatus to feed two or three sheets instead of one.

Increasing the Efficiency of Hydrocarbons.—A process which seeks to increase the heating efficiency, illuminating efficiency and explosive power of hydrocarbons, such as gasoline and naphtha, by the addition of specified materials of low cost is described in patent No. 1,092,461 to Arthur W. Swanberg of Minneapolis, Minn.

Encourages Railway Invention.—U. S. Consul Treadwell of Bristol, England, writes in an interesting way of an undertaking by the Great Western Railway to investigate and patent inventions which relate to mechanical contrivances likely to be useful on railways and suggested by any of the employees. This will doubtless operate as an encouragement to their force of men, but it does not in any way prevent such men from offering their inventions elsewhere. However, it provides for assistance to such men in case they do not find themselves in position to take out patents for railway inventions that may prove of great value. It is reported that other railway companies, appreciating the merits of the scheme, have similar projects under consideration.

A Series of Air Brake Patents.—Spencer G. Neal of Los Angeles, Cal., assignor to California Valve & Air Brake Company of the same place, has secured patents Nos. 1,089,574, 1,089,576, 1,089,577, 1,089,578 and 1,089,579 for improvements in compensating valves and patent No. 1,089,575 for an auxiliary pressure control valve, the several valves having the particular construction specifically described in the patents.

Inventors and Industrial Artists in Congress.—The Society of Inventors and Industrial Artists will hold its fourth international congress in Lyon, France, August 17th to 21st of this year. Among the matters which will be discussed at the congress are (1) International patents; (2) The exploitation of patents; (3) Proper means to encourage inventors; (4) Course and duration of patents; and (5) International deposit of designs and models.

Combining a Steam Boiler with the Oil Burner.—In patent No. 1,089,076 granted to [illegible] Flack of Kansas City, Mo., is shown a steam boiler with an auxiliary [illegible] removably mounted in the [illegible] of the boiler and an oil burner [illegible] to the boiler and [illegible] the auxiliary generator.

Trade-mark Notes

Hosiery and Knit Underwear Same Description of Goods.—In a recent decision Court of Appeals of the District of Columbia in the case of H. Wolf & Sons, appellants, v. Lord & Taylor, appellee, sustained the decision of the Commissioner of Patents supporting the opposition by Lord & Taylor to the registration by H. Wolf & Sons of the same mark for use on knitted and textile undershirts, drawers and union suits of the mark of Lord & Taylor registered for hosiery. In the decision the court said, "Would appellant's use of the mark on underwear lead the ordinary purchaser to believe that he was buying the goods of appellee? We think the word "class," as used in the statute, means broadly a genus, including as species any goods upon which the use of the same mark when on the goods exposed side by side would tend to mislead the purchasing public."

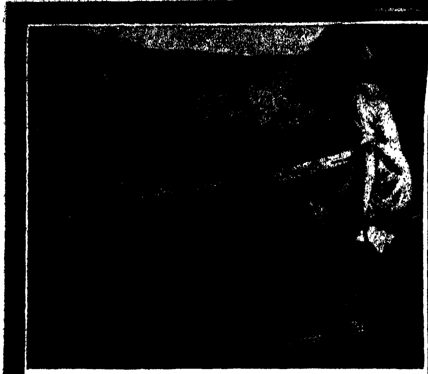
Value of Trade-marks in Central America.—Commercial Agent Garrard Harris, in an interesting communication calls attention to the fact that it is not generally known nor appreciated as it should be by American exporters that trade-marks play a very important part in lower Mexico and Central America, in fact, a leading part in the sale of foreign manufactures, and appears to think that trade-marks have a greater significance in such countries than in the United States. He says it is not difficult to ascertain the value of these trade-marks and trade names in the countries named, as any storekeeper can give the information, and an investigator can obtain abundant information for himself by spending several hours in a store listening to the inquiries of customers who invariably ask for an article by the trade name or the trade-mark by which it is generally known; and if the trade-mark is something they can see and describe, like a star, a crescent, the sun, or a pine tree or any such object, so much the better.

Trade-mark Showing How Goods are Used.—The Court of Appeals of the District of Columbia in affirming the decision of the Commissioner of Patents refusing registration of an alleged trade-mark for "non-metallic electric vehicle tires" in re the Motz Tire and Rubber Company, said: "Moreover, we agree with the Commissioner that the representation of a rim for a tire with a tire thereon, even though the tire be disclaimed, is not registrable as a trade-mark, for the reason that no manufacturer should be prevented from representing to the public the manner in which his goods are used."

Acquirement of Trade-mark Rights.—The Court of Appelas of the District of Columbia in Consumers Company v. Hydrox Chemical Company says, "It is settled law, in this court, that a trade-mark is not acquired by the invention or the discovery of a word or symbol, or by advertising. It only becomes a trade-mark by attaching or affixing it to certain articles of merchandise."

Trade-marks as Applied to Publications Distributed Free.—In *ex parte* The Curtis Publishing Company Assistant Commissioner Newton, in holding the mark patentable, decided that a publication which is distributed free for advertising purposes constitutes merchandise within the meaning of the trade-mark Act and a mark used on such publications is registerable, saying in his decision "They do not pretend to publish this magazine gratuitously, and it is thought that the office should be liberal rather than restricted in its interpretation of what publications are held as merchandise under the trade-mark statute."

The Trade-marks "Grandmas" and "Mothers."—The Court of Appeals of the District of Columbia in affirming the decision of the Commissioner of Patents in Bromund Co. v. Columbia Wax Products Co., *holding that* appellee is entitled to the registration of the word "grandmas" over the prior adoption and use of the word "mothers," in which the Commissioner said the words neither looked alike nor sounded alike, the court said in cases of this kind the evidence of the eyes is more persuasive and satisfactory than any other.



Doubling Your Summer Pleasures

EVERYONE wants to enjoy a vacation to its fullest extent, and to those who are fond of the water there is a means of doubling their Summer pleasures. Picture to yourself a powerful, finely-built motor which can be attached in less than one minute to any rowboat. Picture it driving a rowboat eight miles an hour, a canoe nearly twelve miles, and entirely eliminating the necessity of oars or paddles. Picture any rowboat turned into a rapid motor-boat and you will see the

TRADE MARK
EVINRUDE
DETACHABLE
ROW-BOAT-MOTOR

The motor weighs about fifty pounds and may be carried about like a satchel. It possesses features that no other marine motor can have, because its features are exclusive ones. There are no batteries to carry about because the "Evinrude" is equipped with a

Built-In Reversible Magneto

This magneto is not affected by rain, waves or even complete submersion. It has only one moving part and starts the motor with a one-twelfth revolution of the fly-wheel. The motor is constructed in the same manner as the finest automobile engine made and has won so many prizes for economy and endurance that twelve governments, including the United States, have officially adopted it. **It is built by the largest manufacturers of row-boat motors** in the world, and their **capacity is 60,000 "Evinrudes"** per year. Every motor is absolutely *guaranteed.* Making a motor-boat of any rowboat has enabled thousands upon thousands of people to enjoy the pleasures of motor-boating at a minimum expense. "Evinrudes" are on sale at Hardware and Sporting Goods Dealers throughout the United States.

Large Illustrated Catalogue will be sent Free upon request

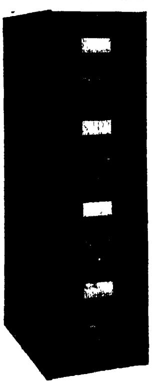
Foreign Notice—OMECO STEEL OFFICE EQUIPMENT is extensively sold abroad. We employ experts in packing for foreign shipments. Catalogs are published in foreign languages.



The Problem of the Hudson River

(Concluded from page 357.)

driven by its own propellers, except within a comparatively narrow belt immediately in the vicinity of the stern.

Changing conditions due to varying widths of channelway were determined by means of vertical walls placed upon the false bottom and held in place by means of bags of sand. Three different widths were examined, i. e., 2,000 feet, 2,400 feet, and the present existing one of 2,800 feet. The moving pictures taken were projected by means of a proper apparatus and upon a scale which permitted them to be studied deliberately and easily. From these data curves were plotted which gave exceedingly instructive information to the experts, and which clearly indicated the extent of the forces and their probable effect.

It would be technically interesting to go into details, but that is not possible here. The net result of the tests showed that a large liner advancing at any speed permitting her navigation against the tide caused lateral disturbances on either side of her extending for a distance of quite 400 feet, i. e., a total danger zone of 800 feet. With increase of speed the force of these perturbations and their menace were augmented proportionately. For vessels moored between piers the effect upon them of passing craft of large size was found to be more serious when the wharves were resting upon open piling than when extending solidly down to the river bed. This revelation had to do particularly with the temporary extension allowed in the case of one of the Chelsea piers for the sheltering of the stern of the "Olympic."

Because of these investigations, the army engineers of the Harbor Line Board emphatically concluded that "the fairway of the Hudson River should not be further decreased, especially in the vicinity of the Chelsea reach." Thus for an outlay of a few thousand dollars data full of warning have been obtained, which may save us from serious mistakes and result, besides, in reducing the dangers to river traffic, and probably mean an economy of many millions of dollars in fuel costs that would certainly have to be borne were the channelway narrowed and tidal velocities augmented.

Dr. Hertoghe on Thyroid Deficiency

AMONG the guests of honor at a dinner given by Dr. William Seaman Bainbridge of the New York Polyclinic Hospital during the recent International Congress of Surgery were many prominent members of the profession, both of this continent and of Europe. The list included Prof. E. Hertoghe of Antwerp; Dr. A. C. Jordan of Guy's Hospital and of the Royal Free Hospital for Chest Diseases, London, England; Dr. Merrill Ricketts of Cincinnati, noted for his researches in intrathoracic surgery; President J. A. Wyeth of the New York Polyclinic Hospital; Prof. Laplace; Dr. Jackson of Philadelphia; Dr. Bruce of Toronto; Dr. Armstrong of Montreal; Dr. Sajous of Philadelphia; Dr. Tinker of Ithaca, N. Y.; and many others.

Prof. Hertoghe, in his after-dinner remarks, gave a most interesting account of his pioneer work in the treatment of conditions due to disorders of the thyroid gland (the gland in the neck, the enlargement of which produces the condition known as goiter). While extreme deficiency of this gland produces unmistakable symptoms, such as dwarfed growth, abnormally low temperature, puffing up of the face, low mental powers (idiocy), in milder cases the symptoms are much less obviously referable to thyroid deficiency, but that this is their true cause is proved by the fact that they yield perfectly to administration of thyroid extract. A number of obscure cases that had baffled physicians were thus made the subjects of spectacular cures. Dr. Jordan showed a number of slides illustrating the use of Röntgen rays for thoracic and abdominal diagnosis, and especially for the diagnosis of "intestinal stasis"—a subject discussed in these pages three weeks ago. Dr. Ricketts illustrated modern advances in surgery on the

Lee PUNCTURE PROOF Pneumatic Tires

No more punctures!

Sounds too good to be true. But the automobilists who sent in the old hardware shown here—and thousands of others—know by happy experience that it is true.

They know that the remedy for tire troubles—for the costly delays that punctures cause—for frequent, expensive inner-tube replacements, is the LEE PUNCTURE-PROOF—*the extra-service pneumatic tire.* Their reports should convince any skeptic.

Free Pamphlet No. 6, "Real Relief for Auto Owners," contains many letters on the service given by "*the tires that put the sure in pleasure.*"

Why gamble with punctures—losing time, patience and money—when with every LEE PUNCTURE-PROOF PNEUMATIC TIRE we give a

Money-Back Guarantee

which assures you freedom from punctures, or the return of every extra cent you paid for insurance against them? You can't lose—you have everything to gain. Write to-day for this Pamphlet No. 6, giving full data on the *experience of users*; the exact wording of that *guarantee*, the details of construction (with 300 or more discs of armor-steel, imbedded in rubber, overlapping with heavy fabric between—making friction and heating impossible); *the live, extra dense, double-tough*

"Vanadium" Rubber

(used *only* in the Lee factory) which assures longer life, greater resiliency and comparative freedom from oil-rotting.

LEE TIRE AND RUBBER COMPANY

brain and heart, organs which until lately generally were thought almost too vulnerable to permit of operative intervention.

John Henry Poynting

THE world of physics mourns the death of John Henry Poynting, who passed away on March 30th, at his home in Birmingham, England.

Of Poynting's scientific researches no doubt the most important are his contributions to the theory of the electro-magnetic field. In two memoirs, "On the Transfer of Energy in the Electro-magnetic Field" and "On the Connection Between Electric Current and Electric and Magnetic Inductions in the Surrounding Field," he has shown that the flow of energy in such a field takes place in a direction perpendicular both to the lines of electric and also of magnetic force, and can thus be represented in direction and magnitude by a certain vector, which has become known as *Poynting's vector*. The wire "carrying an electric current" is seen to be merely a guide for the electrical energy flow—the flow itself takes place along lines which permeate the entire space about the conductor, and abut perpendicularly against the wire. The energy, so far from "flowing along" the wire, is propagated sideways into it from the surrounding space.

During the later years of his life Poynting devoted much of his attention to the subject of radiation pressure, to which he made important contributions both in its theory and in experiment. He demonstrated the tangential pressure of light, and showed that a beam of light behaves essentially like a stream of momentum. He showed that radiation pressure, though small, plays an important *rôle* in cosmic phenomena. Turning to other aspects of the subject of radiation, he indicated means for determining the temperature of celestial bodies and interstellar space. Of his earlier work the chief was his determination of the general constant of gravitation by means of an ordinary precision balance with an adjustable mass placed under one of the pans. In this way the effect of the adjustable mass was compared with that of the earth itself, so that one is justified in describing the experiment as "weighing the earth."

Poynting was the author of numerous other scientific papers, and the joint author with Sir J. J. Thomson of a series of textbooks of physics. He also published several books of a more popular character.

Poynting was connected with Birmingham University (then Mason College) since its birth, in 1880, and on the coming of age of the institution, in 1901, he was appointed dean of the faculty of science. This office he held until recently, when ill health forced him to restrict his work to his professorial duties.

As a teacher Poynting will be remembered by his pupils as a man possessing in a singular measure the faculty of stirring interest and training the mind to rigorous thinking. Just what such influence means only those know who have actually experienced it.

The principal honors that came to Poynting in the course of his career may briefly be sketched here. At the mathematical tripos he was bracketed third wrangler in 1876, and later gained the Fellowship of Trinity College, Cambridge. In 1888 he was elected Fellow of the Royal Society, whose gold medal was awarded to him in 1905. In 1891 he received the Adams prize, and in 1899 he was made president of section A of the British Association. The meeting of that year is memorable for the announcement, by J. J. Thomson, of the separate existence of electrons. In 1905 Poynting was chosen president of the Physical Society.

We have spoken of Poynting as the investigator and the teacher. Those who knew him as a man need not to be reminded on this occasion of the qualities which endeared him to those so privileged. That modesty and freedom from all hauteur which is the surest sign of a truly great mind, was among the most marked traits of his character. A balance of mind which is not always found in those who [illegible] prominence in special fields rendered invaluable his opinions and judgments in matters of weight. His heart was as great as his mind. A. J. L.

Air Craft on the Defensive and Offensive

A Review of Recent Experiments

FRANCE is zealously striving to adapt the flying machine to aggressive warfare. Among others, there were begun at the flying field at Buc in October, 1913, tests before a military committee with the so-called "Air Craft Hunter" of Lieut. Mailfert. The flying machine, which was already exhibited at the last Aeronautic Exhibition in Paris, is a Nieuport monoplane of 160 horse-power. It contains in its *fuselage* a shot-sieve or a projectile thrower, an arrangement which, when the pilot sets it in action, strews the underlying ground with two thousand shot. An aiming arrangement is said to be at hand. On the flying field a flying machine was represented to actual scale by means of a disk. Lieut. Mailfert rose in his machine to a height of 2,000 meters and flooded the target with his projectiles. The disk was riddled with many bullets. Then free balloons were released, against which also Mailfert brought his shot sprinkler into action. He succeeded in causing two balloons to sink.

Another kind of aggressive flying machine, the so-called "Zeppelin-Hunter," was put to trial last summer, according to the Paris *Journal*. With its own weight reduced to a minimum, it had to carry an armor of 60 to 70 kilogrammes to protect both the pilot and the more vulnerable parts of the machine. *It is* intended to provide the flying machine with a light machine gun, which can perforate the Zeppelin hulls with rapid fire shot and ignite the gas.

In January, 1914, an experiment took place also in Villacoublay, with a new armored flying machine, which was built and provided with a rapid-fire gun, according to the directions of the heads of military aeronautics. The ordnance, presumably a machine gun, is claimed to have signal striking capacity. The flight, however, which the pilot, Espaner, effected with the new aeroplane, was not very fortunate.

The French papers emphasise that in future all French military air craft, except the school machines, will be armored to protect them against hostile fire. They may be divided into the following kinds:

1. Armored monoplane for reconnoitering artillery and cavalry. Minimum velocity, 120 kilometers per hour.
2. Armored biplane for reconnoissance work of the general staff at great distances. Minimum velocity, 100 kilometers per hour.
3. Armored biplane which, provided with machine guns, etc., shall destroy hostile aeroplanes and airships. Minimum velocity, 120 kilometers per hour.
4. Large aeroplanes with more seats, for special service.

The Paris Aeronautic Exhibition last fall showed a special number of armored aeroplanes. The armor protection extended not only to the pilot and observer, but also to the provisions, the rudders, the measuring instruments and especially the propulsion system. The aeroplanes not intended for aggressive warfare were for the most part provided with wireless apparatus.

The improvement in the possibility of observation was shown at Villacoublay late in November, 1913, on a new kind of aeroplane in which the seat for the observer is placed forward, directly under the screw propeller. Deputy Girod, piloted by Gobé, flew over the field several times and made effective observations. The capacity for observations from this position is without doubt greater, still the observer in this advanced position is more exposed to hostile fire, and above all is incapable of taking charge of the controls of the aeroplane in case of failure of the pilot.

At Farnborough in England last year a trial of sharp-shooting from aeroplanes was held. A military biplane was provided with a machine gun and ammunition; this gave, from an elevation of 120

"Oh! I always use plenty of oil!"
Does that insure correct lubrication?

NO!

A low-*quality* or wrong-*bodied* oil, no matter how freely it is used, can never do the work of the correct lubricant.

"Plenty" of too-*light* oil often leads to loss of compression and escape of explosion. This means loss of power and unnecessary consumption of gasoline.

"Plenty" of too-*heavy* oil will often fail to distribute properly through your feed system. Excessive friction, burnt bearings and carbon trouble will result.

"Plenty" of low-*quality* oil simply means plenty of imperfect protection for the moving parts.

The absolute necessity for oil whose "*body*" is correct for his motor and whose *quality* will show maximum lubricating efficiency is entirely overlooked by the motorist who says:

"Oh! I always use plenty of oil."

By guess-work and luck you may *sometimes* get oil for your motor which is correct in "*body*," and efficient in "*quality*." You *should* be using such oil *continuously*.

You can be sure of it by using the grade of Gargoyle Mobiloils specified for your car in the Lubricating Chart on the right.

Make a note of the grade specified for your car. Then make sure that you get it. If your car is not mentioned, send for our complete Lubricating Chart.

This standard guide to correct lubrication was prepared after a careful analysis of every make and model of car. It represents the professional advice of the world-leaders in scientific lubrication—the Vacuum Oil Company.

On request we will mail a pamphlet on the Construction, Operation and Lubrication of Automobile Engines. It describes in detail the common engine troubles and gives their causes and remedies.

The various grades of Gargoyle Mobiloils, purified to remove free carbon are, are:

Gargoyle Mobiloil "A,"
Gargoyle Mobiloil "B,"
Gargoyle Mobiloil "E,"
Gargoyle Mobiloil "Arctic."

They can be secured from reliable garages, automobile supply houses, hardware stores and others who supply lubricants.

It is safest to buy in original barrels, half-barrels and sealed five and one-gallon cans. See that the red Gargoyle, our mark of manufacture, is on the container.

For information, kindly address any inquiry to our nearest office. The city address will be sufficient.

Correct Lubrications

Explanation: In the schedule, the letter opposite the car indicates the grade of Gargoyle Mobiloil that should be used. For example, "A" means "Gargoyle Mobiloil A." "Arc" means "Gargoyle Mobiloil Arctic." For all electric vehicles use Gargoyle Mobiloil "A." The recommendations cover all models of both pleasure and commercial vehicles unless otherwise noted.

Maximum Lighting Efficiency

For Offices, Stores, Places of Amusement and Public Assembly, Hotels, Restaurants, Factories, Churches and Libraries

Minimum Current Consumption

The Brascolite is not a new kind of bulb but a fixture (patented)—it is the principle on which this fixture is constructed that makes it so efficient—giving a shadowless, white, uniform, soft light—producing better and more complete illumination with fewer light units and, therefore, less current consumption. Look at the picture—the bowl diffuses the light rays—the depolished plane above the bowl reflects them—the combination throws the light evenly over a very wide area; making Brascolite more efficient than direct reflected light and 50% more efficient than indirect lighting (by Photometric tests). The

TRADE MARK

BRASCOLITE

DIFFUSION PLUS REFLECTION

system is daily being installed to *replace* both direct reflected and indirect lighting systems—architects and lighting engineers are specifying Brascolites for new buildings.

Try A Brascolite For 60 Days

in your library, billiard room, hall, vestibule or private office —this intimate use will enable you to judge of its efficiency—convince you that it's needed in your business offices, store, etc. Your dealer will install the light—try it 60 days—if not satisfied return it and get your money back If satisfied and you order Brascolites for business equipment totaling $100.00 your dealer is authorized to refund to you the purchase price of your trial light.

What is your Business? Check off on list below and mail to us so we may send you specific information on Brascolites designed to fit your exact business needs.

Factory, owner, manager; **Office Building**, owner, manager; **Head of Large Office Force**, **Theatre, Hall, Restaurant** or other large assembly place; owner, manager; **Hotel**, owner, manager; **Club**, manager, board; **Church**, clergyman, vestryman; **Library**, **Hospital**, superintendent, head nurse; **Store**, owner, manager; **Architect**, **Electrical Engineer**; **Power Plant**, owner, superintendent. Any place where good light is essential to good work or comfort of patron or employee.

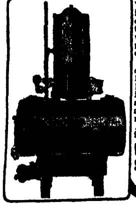
Distilled Water For All Purposes

Laboratories, schools and colleges, hospitals, clubs, bottlers, manufacturing and wholesale druggists, medical manufacturers and all other users may now have absolutely pure water at trifling cost with a

Polar Water Still

Designed for particular needs and made in *small or large capacities. Gas, oil or steam* operated. A Polar Water Still makes it possible for offices and factories to have pure water for drinking purposes economically.



Cities of 5000 and over will support a Distilled Water Business. A small investment insures a steady and profitable business, summer and winter. Ask for complete information.

Polar Water Still Company
8 N Michigan Ave.
CHICAGO

And you can't get THIS DESIGN except in

The "TEMPLE" ENGINE

I don't have to tell you that VIBRATION and FRICTION cause tremendous wear and tear on an engine—besides wasting power, fuel and money. You know that.

But let me say this: that the "TEMPLE" Engine Design is the only one that really masters these ruinous forces. It does this by placing the Cylinder and Piston in a vertical position, with the head right down on the low, flat base (an exclusive "TEMPLE" feature.)

The shock and strain of explosions are, therefore, fully 80 per cent less than in engines having their Cylinder-Head or Explosion Chamber up in the air, above a high, wobbling base.

The "TEMPLE" vertical piston action—combined with especially designed gravity lubrication system (by which lubrication is supplied exactly when, where and in quantity required)—almost entirely eliminates friction, and makes possible the economical, trouble-free delivery of a STEADY STREAM OF MAXIMUM POWER.

These special "Correct Design" features (joined with others made possible by them) make the "TEMPLE" run more quietly and smoothly—deliver more and steadier power—use 1-3 to 1-2 less fuel—weigh 1-3 to 1-2 less—have 2-3 less bulk—occupy 1-3 to 1-2 less space—more portable—wear less and last longer—than other engine types.

You simply CAN'T GET "TEMPLE" RESULTS in the [illegible] cylinder designs. If you want [illegible] POWER—to run a Thresher, Grist Mill, [illegible] Shredder, Husker, Sprayer, Pump or any other INDOOR or OUTDOOR machinery requiring 2 H. P. to 50 H. P.—write to me at once. I'll tell you some other things, you never knew before, about correct engine DESIGN—something that may be worth hundreds of dollars to you in engine SERVICE.

Kenneth Kennedy, Temple Mfg. Co.
(Formerly with U. S. Eng. Wks.) 3166 S. 54th Ave., Cicero, Ill.

meters, 20 shots directly downward. As to its striking capacity and effect, nothing has been reported; the recoil from the shot was without notable influence on the equipoise of the aeroplane.

Also a Birmingham society instituted at Bisley sharp-shooting at an aeroplane with a machine-gun. The 25-pound, air-cooled machine-gun invented by Col. Lewis was fixed on a tripod on the aeroplane framing; on a tripod was also placed the movable seat for the protection of the aviator. Out of thirty shots at a target space of 20 feet, 11 hits were scored. From what elevation the aeroplane fired has, however, not been reported, nor the velocity of the air craft, nor the kind of target arrangement.

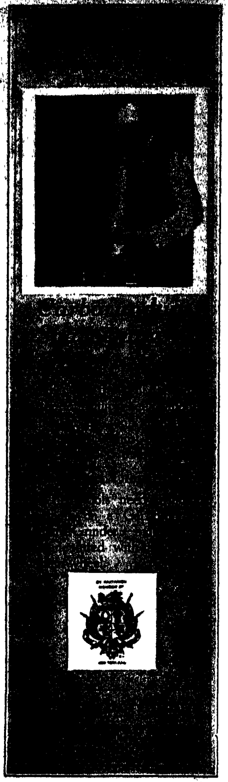
A sighting arrangement for machine guns on air craft has lately been patented. The machine gun is fixed between the legs of the observer sitting forward and having charge of the gun. The aviator sits elevated behind the observer. The fore part of the aeroplane is covered with a hood which carries on top a notch and sight. When the target is in sight the observer calls to the pilot and adjusts the sighting arrangement for distance and altitude. The aviator directs the aeroplane at the target by use of the rudders in conjunction with the notch and sight. When the observer perceives that the direction coincides he promptly fires.

An aeroplane projectile with rear rudder has been made in England. A tube extends lengthwise through the middle of the cylindrical projectile, filled with explosive. It carries, in front, trigger pins and percussion caps separated by an interspace, and having well to the rear an ignition charge. Both parts are secured by bolts fixed to the aeroplane frame, and, through the projectile, interlock in the tube, and so protect the aeroplane from destruction by its own discharge due to hard landing, shocks, etc. The part of the tube extending to the rear of the projectile carries the tail rudder. The projectiles hang on two hooks perpendicular to the floor of the aeroplane frame. When the projectile is to be thrown, the aviator establishes a special relation between the measured altitude and the velocity of flight, aims at the target, and, by means of a hand lever, releases the supporting arrangement of the projectile. The projectile, now free, sets itself point downward by means of its tail rudder. Since the two safety bolts have remained behind in the aeroplane, the igniter is in working condition, and when the projectile strikes, the trigger pin pierces the percussion cap, ignites the ignition charge, and this sets off the explosive charge of the projectile.

Shooting at aeroplanes was carried on last year in the camp at Chalons. A kite seven meters in width by six meters in length, represented an aeroplane and was towed by an automobile and wire cable with a velocity of 60 kilometers per hour. It was fired at by two squads of infantry, of fifty men each, at a distance of 800 to 900 meters. Out of nine hundred shots (nine cartridges for each man) twelve hits were scored on the kite, that is 1.3 for each man. A second shooting, with the same number of men, at a small kite, measuring 1.5 meters broad by 1 meter long, gave 0.5 shot per man, but at a distance not reported. Machine guns were trained against the same target, but with less effect.

A Spanish aeroplane was hit last November by Maroccans. Capt. Barreiro and Lieut. Gil-Rios undertook, in a reconnoissance on a military biplane, to observe the position of the insurgents. In this they were subject to fire by a group of hostile troops which had got footing on Conical Mountain. The lieutenant was grievously injured by two shots, the captain was wounded by one shot. It was possible for the officers, in spite of their wounds, to fly back again to their own camp—a proof, therefore, that even effective fire does not always put an aeroplane out of commission, and that an energetic aviator, even in spite of his wounds, will often carry out his orders.

[Translated for the SCIENTIFIC AMERICAN from Kriegstechnische Zeitschrift.]



2 H.P. AMERICAN $38
Marine Motor Only

Just the thing for the average family launch. It's compact, easy to install, easy to operate. Women and children can run it with perfect safety. No cams, gears or springs to get out of order or need adjusting. Runs in either direction. Has wide range of speed. Can be furnished for gasoline or kerosene. To start, simply turn on fuel and switch, rock the fly wheel and away you go. We also build other sizes up to 30 h. p.—one to four cylinders. Every one is of such perfect design and made of such good materials that we guarantee them for life. You take no chances with an American. Send for beautiful, new catalog today.

Patents Which Expire in 1914

THE United States patents issued in 1897 for seventeen years will expire on corresponding dates in 1914. Among the important patents which will expire in 1914 are as follows:

In machines for cultivating a number of rows of crops is the patent to Davis, 576,059, January 26th, 1897; the swing or hammock cultivator patent to Sobey, 578,502, March 9th, 1897; the harrow patent to Sharp, 589,797, September 7th, 1897, and that to Ryder, 585,941, July 6th, 1897, which shows harrow teeth and supporting wheels at right angles on rocking tooth bars, so that as one device is thrown out of operation the other is thrown into operation; the check rowing, drilling and hand dropping planter patents to Lindgren, 577,487, February 23rd, 1897, and to Dooley, 593,295, November 9th, 1897; the Eltsroth patent, 579,049, March 16th, 1897, for a broadcast seeder in the form of an attachment that can be substituted for the end board of an ordinary farm wagon; the corn harvester patent to Ellis and Stewart, 577,105, of February 16th, 1897; the Sauer, 576,510, February 2nd, 1897, relating to the production of various kinds of wine from malt by the aid of properly selected grape ferments; the Swenson patent, 591,304, October 5th, 1897, for the volute type of cotton press; the Lowry patent, 581,601, April 27th, 1897, for a cotton press in which the cotton is fed under great pressure through a rotating head, also the Lowry cotton press patent, 581,600, of April 27th, 1897; the Hudson, 587,826, of August 10th, 1897, for a cigarette machine in which the ends of the paper are tucked around the tobacco as in certain handmade cigarettes; the Campbell, 579,422, of March 23rd, 1897, for making the well-known elliptical cigarettes; the cigar machine patent of Bunn, 579,859, of March 30th, 1897, in which the rollers are composed of short sections to adapt them to fit various forms of bunches; the Underwood patent, 591,436, of October 12th, 1897, for tobacco leaf stemmer in which the leaf is fed stem first between the stripping rolls until gripped by gripper rolls; the Fargo patent, 583,143, of May 25th, 1897, combining a churn and a butter worker; patent to Vidal, 594,105, November 23rd, 1897, for an artificial die made by heating synthetic substances with sulphur and sodium sulphide; the Tiemman's patents, 583,719 and 583,720, of June 1st, 1897, relating to improvements in synthetic perfumes, the patents being for aromatic ketones; the artificial camphor patent to Nagel, 582,221, of May 11th, 1897; the patent to Constam, 579,317, March 23rd, 1897, for a process of making percarbonates for bleaching purposes; the Carr patents, 583,565, of June 1st, 1897, and 581,335, April 27th, 1897, for dental bridge-work; the Wildprett patent, 577,866, of January 26th, 1897, for ladders for store service; the Knight patent, 587,442, of August 3rd, 1897, for a simple scheme for the transition of two or more electrical motors which may be connected in series, in parallel or in any relation of series and parallel; the Schimpf, 582,237, of May 11th, 1897, for the application of electricity to agriculture apparatus; the Cox patent, 585,257, of June 29th, 1897, for electric meter to give different readings in accordance with the rate of charges where different rates for electric service are charged; the hydraulic motor patent, 595,027, to Westinghouse of December 7th, 1897, in which a rotary pump connects with the two ends of the power cylinder and pumps the water from one end of the cylinder to the other to move the piston; the hydraulic press patents to Parfitt, 579,441, March 23rd, 1897, and to Winans, 582,836, of May 18th, 1897; the patent to Gulick, 579,265, March 3rd, 1897, for clamping means for the tubes of bicycles; the Forg patent, 581,907, of May 4th, 1897, for reducing weight in parts of bicycle constructions; the motorcycle patent, 583,809, of June 1st, 1897, to Libbey; the Streeter patent, 595,588, of December 14th, 1897; the Sargent patent, 587,408, of August 3rd, 1897, and the [illegible], 590,920, of [illegible], 1897, for brake-shoes for [illegible] [illegible]; the [illegible] patent, [illegible], of June 15th, 1897, for steel hopper-bottom cars; the Hardie patents, 577,024, of February 16th, 1897, and 580,827, of April 3rd, 1897, in which the car or locomotive reservoir in air storage motor cars is charged from a stationary plant; the electric motor-vehicle patents of Morris and Salom, March 30th, 1897, 579,890; Maxim patent, November 30th, 1897, 594,805; Woods patent, June 29th, 1897, 585,871; the patent to Morris & Salome, 578,651, of March 9th, 1897, in which separate motors for the driving wheels, for ease in turning motor vehicles, is shown; the patent to De Dion & Bouton, 593,877, November 16th, 1897, for a sparking igniter, and the patents to Westinghouse and Ruud, 583,584, 583,585, and 583,586, of June 1st, 1897, for charge feeding, speed regulating and igniting mechanisms for gasoline engines; the Maxim patents, 593,227 and 593,228, of November 9th, 1897, for automatic heavy ordnance; the patents to Browning, 580,923, April 20th, 1897; Ehbets, 580,935, of April 20th, 1897; to Manlicher, 581,295 and 581,296, of April 27th, 1897; to Mauser, 584,479, June 15th, 1897, and to Burgess, 589,120, of August 31st, 1897, for fire-arms (small arms); the Gathmann patent, 583,042, of May 25th, 1897, for projectile in which the explosion of the detonator is rendered harmless, being contained in a relatively large chamber and separated from the bursting charge by a movable metal barrier; the Schlick patent 594,288, November 23rd, 1897, for compound marine engine; the Symington patent, 581,789, of May 4th, 1897, for preventing compression in locomotive cylinders when drifting; the Curtis steam turbine patent, 590,210, of September 21st, 1897; the lubricator patent to Jones, 584,688, of June 15th, 1897, in which the feed of lubricant is automatically controlled by variations in the periods of its action; the Bowen patent, 583,668, of June 1st, 1897, showing an oil cup; the Porter and Hennessey, 587,272, of July 27th, 1897, for lubricator in which the oil is displaced by condensation of steam; the fuel briquetting patent to Batter, 580,568, of April 13th, 1897; the patents for acetylene machines in which carbide is fed to water as in patents, 575,281, to Buffington, January 12th, 1897; to Fuller, 575,474, January 19th, 1897; to Deuther, 567,955, February 9th, 1897; and to Rhind, 583,582, June 1st, 1897; Altenbaugh patent, 584,138, of June 8th, 1897, for a glass machine in which glass is gathered from a tank or furnace and delivered to a mold for making tumblers; the Hay patent, 582,587, May 11th, 1897, for an improvement in the utilization of the heat of cooling clinker of a cement kiln; the Garchey patent, 587,800, August 10th, 1897, for making imitation stone from waste glass; the Goldsmith patent, 578,868, of March 16th, 1897, for process of reducing refractory oxides; the patent to Abbott, July 27th, 1897, for machine for automatically forging horse-shoe nails; the patents to Locke, April 13th, 1897, 580,579, and to Viellard and Oswald, 580,564, April 13th, 1897, for automatic machines for cutting, bending and shaping links for drive chains from a continuous strip and assembling them into a chain; the gear cutting machine patents to Fellows, March 30th, 1897, 579,708, and to Warren, 588,738, of August 24th, 1897, in which the cutter bears to the blank being cut the relationship of an intermeshing gear; the incandescent gas mantel patent of Cortis, May 4th, 1897, 581,879, in which the life of the delicate mantel is prolonged by carrying the burner on springs; the Fuller patent, 580,126, April 6th, 1897, for burner designed to burn acetylene gas; the Cornell patent, 599,792, of March 30th, 1897, for machine for pasting labels on bottles, in which the label is sprayed with an adhesive and then spread upon the bottle; the patent, 583,072, May 25th, 1897, to Munson for making shucks for match boxes by refolding; the Noble patent, 586,054, July 6th, 1897, for machine for making paper tubes by forming continuous tubing by a spiral wind; the Potter patent, 574,498, January 5th, 1897, for printing press, including means for associating delivery and folding the product of the rotary press; the Harris & McNutt patent, 577,405, February

Cadillac
Standard of the World

PRICE is not the consideration with the majority of those who purchase Cadillac cars.

They can afford to possess any car, no matter what its price.

They are influenced by the prestige of Cadillac ownership.

They are influenced by Cadillac sturdiness and Cadillac dependability.

They are influenced by the economy of operation and maintenance.

They are influenced by the minimum depreciation after years of service.

They are influenced by the super-luxury and the super-quality of the car.

They are influenced by the super-smoothness in its running.

They are influenced by the service which the Cadillac affords.

They are influenced by the conviction that the Cadillac provides in surpassing measure, all of those qualities which make motor car ownership desirable.

16th, 1897, for rotary printing press, especially adapted for printing on cards and envelopes; the Wood patent, 589,519, September 7th, 1897, for means for preventing the off-set of fresh reprinted ink in printing presses; the typesetting machine patent to Ennisson & Honiss, 583,224, March 25th, 1897, which selects proper justifying spaces from a magazine; the type distributing machine patent to Cox, 578,216, March 2nd, 1897; the Dexter patent, 588,635, August 24th, 1897, in book-binding; the patent, 580,111, of April 6th, 1897, to Jacobs for machine for applying cloth book covers; the Johnson patent, 584,363, June 15th, 1897, for linotype machine improvement; the patent to Skursheedt et al., 591,079, October 5th, 1897, for mechanism for automatically feeding and stitching spangles to a foundation fabric; the patent to Reed, 580,531, April 13th, 1897, for a wood-turning machine for turning shoe lasts; the Fischer patent, 595,911, December 21st, 1897, for electrically operated clocks; the patent to Kellog, 591,169, October 5th, 1897, for automatically operating time-operated mechanisms; the patent to Brachhaussen, 596,393, December 28th, 1897, for automatic musical instrument; the musical instrument of Cahill, 580,035, April 6th, 1897, in which electrical vibrations corresponding to the notes of the musical scale are produced and combined by keyboards to correspond to chords collected on wire and transmitted to loud speaking telephones; the Olivary patent, 583,077, May 25th, 1897, for changing the pitch of larinates by partly filling the bore without affecting the finger holes; the patents in optics to Armat, 578,185, March 2nd, 1897, and Abbe, 584,976, June 22nd, 1897, the patent to Holport, 579,434, March 23rd, 1897, for boat lowering and detaching device adapted to release the boat on its being water borne; the Sinty patent, 581,625, April 27th, 1897, for reversing the angle of screw propeller blades for use with non-reversible engines; the Kaselowsky patent, 591,768, of October 12th, 1897 for automatic steering devices for boats adapted to operate on the principle of the gyroscope; the patent to Curtiss, December 28th, 1897, 596,294, for safes in which the dogging devices are held normally inoperative by thermostatic device released upon a rise of temperature; the all-glass show case patent of Ganter, 584,584, June 15th, 1897; the patent to Hale, 595,624, December 14th, 1897, for mechanism for reversing car seats, and the Johnson patent, 582,926, of May 18th, 1897, for artificial sponges for surgeons' use.

Napier Tercentenary Celebration, July, 1914

JOHN NAPIER'S *Logarithmorum Canonis Mirifici Descriptio* was published in 1614; and it is proposed to celebrate the tercentenary of this great event in the history of mathematics by a congress, to be held in Edinburgh on Friday, 24th July, 1914, and following days

The celebration is being held under the auspices of the Royal Society of Edinburgh, on whose invitation a general committee has been formed, representing the Royal Society of London, the Royal Astronomical Society, the Town Council of Edinburgh, the Faculty of Actuaries, the Royal Philosophical Society of Glasgow, the Universities of St. Andrews, Glasgow, Aberdeen, and Edinburgh, the University College of Dundee, and many other bodies and institutions of educational importance.

Through the SCIENTIFIC AMERICAN, the president and Council of the Royal Society of Edinburgh have now the honor of giving a general invitation to mathematicians and others interested in this coming celebration.

The celebration will be opened on the Friday with an inaugural address by the Rt. Hon. Lord Moulton, F.R.S., LL.D. (Edin.), etc., followed by a reception given by the Right Honorable the Lord Provost, magistrates and Council of the city of Edinburgh. On the Saturday and Monday the historical and present practice of computation and other developments closely connected with Napier's discoveries and inventions will be discussed.

A memorial service will be held in St. Giles's Cathedral on the Sunday.

Among many who have expressed a warm interest in the celebration and who hope to take part in the congress, may be mentioned Prof. Andoyer, Paris; Prof. J. Bauschinger, Strassburg; Prof. Hume Brown, Historiographer Royal for Scotland; Prof. F. Cajori, Colorado, U. S. A.; Prof. G. A. Gibson, Glasgow; Dr. J. W. L. Glaisher, Cambridge; Prof. Lang, St. Andrews; Prof. Macdonald, Aberdeen; Prof. E. Pascal, Naples; Prof. Karl Pearson, London; Prof. Eugene Smith, New York; Prof. Steggall, Dundee; Prof. Whittaker, Edinburgh.

Merchiston Castle, the residence of Napier, has long been occupied by the well-known public school, which draws pupils from all parts of the British Empire. The governors of the school have kindly invited the members of the congress to visit the castle and grounds on the Saturday afternoon.

Relics of Napier, collected by Lord Napier and Ettrick and other representatives of the family, will also be on view; and it is intended to bring together for exhibition books of tables and forms of calculating machines which may reasonably be regarded as natural developments of the great advance made by Napier.

Individuals, societies, universities, public libraries, etc., may become founder members on payment of a minimum subscription of £2; and each founder member will receive a copy of the memorial volume, which will contain addresses and papers read before the congress, and other material of historic and scientific value. It is important to secure as many founder members as possible, so that a volume may be brought out worthy of the memory of Napier.

Ordinary subscribers (5s.) attending the celebration may receive copies of the memorial volume at a reduced price.

Subscriptions and donations should be sent to the honorary treasurer, Mr. Adam Tait, Royal Bank of Scotland, St. Andrew Square, Edinburgh.

All who are interested in this proposed celebration are respectfully invited to communicate with the general secretary of the Royal Society of Edinburgh, 22 George Street, Edinburgh, and to announce their intention of being present.

Sound Perception v. Deafness

By Stanley Robinson

VERY few people are aware of the fact that totally deaf persons are really conscious of the noise they themselves make, or of the noise made by other persons or things, when such noises are made near enough to be communicated to their bodies.

The fact that the deaf, scientifically speaking, possess diaphragmatic hearing is known only to their friends and instructors. They hear, or rather feel, the concussion of many sounds almost as well as hearing people, through the vibrations on their ear diaphragms, these vibrations reaching the brain through the medium of the nerves of feeling.

I have not a particle of hearing myself, and write chiefly from my own experience, knowledge, and life-long association with the deaf. A totally deaf person is much like a man with his ears plugged up with cotton and thickly bandaged. Were the bodies of deaf mutes not sensitive to such sounds and noises as they feel or come in contact with, I fear they would be in a sphere of too great a silence. Noises make the deaf feel that they are not really deaf. Strange to say, sounds are often troublesome. The deaf often feel grateful that they can enjoy the benefit of so much silence as they do. Much of the time they are undisturbed by all the harsh sounds which agitate the ears of the hearing community.

Such sounds as are perceived or the sounds that come in constant contact with the persons of the deaf are often a help rather than a bother.

If you are told that the gentleman standing at your doorway is totally deaf, do not imagine that he can hear when you see him turn to look at a [illegible] truck. The noise of the truck on the cobblestones has simply been communicated to the man's body by vibrations. Had it been a rubber-tired vehicle drawn by a team of horses, the man would have been unconscious of its presence, because rubber-tired vehicles, as a matter of fact, produce no vibrations, and very little noise. The footsteps of the horses do not cause a sufficient noise for the man to feel, as they are too far away from him. The footsteps of a horse may be distinctly felt by a totally deaf person, provided he is near or within the required distance to feel the sound. The distinctness of the sound depends very much upon the kind of material on which the horse is walking. Thus if a horse is stamping on soft ground in order to remove an annoying fly, and the totally deaf man is but a few feet from him, the noise will appear to the man, for he will feel it as a dull thud. If, however, the horse is stamping or walking on a boarded surface, or platform, the deaf man will exclaim, "Oh, what a noise!"

Vehicles produce no vibrations when the streets are covered with snow or mud. Consequently, they are just as noiseless as rubber-tired vehicles. A deaf mute may pass throngs of people on the street, and yet not feel the sound of a single footstep. The only noise he will perceive will be the rumbling of some passing vehicle, also on an unpaved thoroughfare the sound of wagons or heavily laden trucks can scarcely be felt.

In many ways stone is a poor material for the conduction of noises to the body of a deaf mute. He will not feel the noise if you stamp on a stone pavement unless you are close to him.

A deaf mute will be conscious of all the noise in the room which he occupies He will feel the door slam, the fall of a ball, an apple, an orange, a key, or any other weight, the footsteps of persons in the room, if it is not carpeted, or if they do not have on rubber shoes or slippers; also the noise he makes with his own knife and fork when eating

Shortly after I became deaf, at the age of ten, I did not realize that my deafness was total, simply because through my sense of feeling I was still familiar with most sounds. But when I could not feel human voices, the fact was clearly established that I had not a particle of hearing left. A deaf man feels sounds better when they are near or when he has hold of hollow bodies, such as empty boxes, closets, iron or wooden pillars, which take sound vibrations better than solids Placing my hand on the panel of a closet door, I am able to feel faintly the thundering noise of a bass drum three hundred feet or more away. I can scarcely perceive such a deafening noise the same distance when standing against a wall of stone

Door Bells and Alarm Clocks.

A deaf person never feels the sound of a bell as its vibrations are confined solely to the atmosphere. I think there is no way by which the sound of such an instrument can be imparted to our feelings. On account of this draw-back every deaf mute who lives alone finds it necessary to arrange some kind of a device which will serve him either through his sense of vision or his feelings, as suitably as the ringing of the door bell serves any hearing person. Many of these devices, only a few of which I shall describe here, are very ingenious and novel as well as useful.

Deaf mute parents that have hearing children or hearing persons living with them, of course, need no substitute for their door bell. Families whose members are all deaf, or who have no hearing persons living with them, often have a dog whose barking and actions, when the bell rings, "hears" for them. Families that reside in houses that are no better than fire traps should always be ready to escape and save their lives in case of fire.

We do not always feel safe when asleep, because if a fire should occur we would not know it or would not be aroused in time by persons trying to save us by knocks and kicks at our door. Only a few months ago the school for the deaf at Malone, N. Y., was destroyed by fire, but as the pupils were well drilled to meet such an emergency, no one was injured.

The De Luxe Business Paper
OF THE AMERICAN BUSINESS MAN

COUPON Bond is something more than a mere sheet of good paper.

There is behind it over half a century of tradition in the making of a fine bond paper in one mill.

Its makers have given to it their best, and its perfection expresses pride in their product.

COUPON BOND
One of the "Eagle A" Watermarked Papers

And so Coupon Bond, because of its quality, character and impressiveness, is used by American Business Men who find a keen, personal satisfaction in using a business paper which best reflects their personality.

Coupon Bond overcomes the impersonality of cold type.

It tells of the dignity of the house that uses it, and puts the seal of standing upon both letter-heading and signature.

If you are interested in the business-building power of good stationery send for our portfolio of Coupon Bond Samples

BUY INDESTRUCTO BAGGAGE

Compare the Indestructo with any other trunk made. See it side by side with other trunks in the stores.

You will find that *not one* of them has the distinctive features of the Indestructo—that not one of them gives you the same solid assurance of real worth and service—not one of them is so well able to care for itself in the crash and crush of hard baggage handling.

One proving bit of evidence as to the standing of Indestructo Trunks in the business world is the way leading merchants—the best and wisest merchants have accepted the Indestructo.

Remember that no other trunk can give you the service, satisfaction, the beauty and lasting value, and the special Five Years' Insurance and Registry features that are all yours with the Indestructo Trunk. It is worth your while to buy right and be satisfied. Say to yourself, "The next trunk I buy will be an Indestructo"—then make good on that promise.

Our booklet explains that fully—ask for it.

National Veneer Products Company

THE MARK
Cold Drawn Steel Union

Here at last is a pipe union that will not leak, will not rust, will not crack under the wrench or under high pressure—the ideal union

Simply because it is Cold Drawn Steel and not malleable iron or some other form of casting.

Pipe manufacturers don't try to furnish malleable or cast iron couplings with their pipe — they use **wrought** couplings, and it is only because nobody had been able to make pipe unions from wrought steel that the use of malleable iron or cast brass has ever been permitted in pipe unions

The Mark Cold Drawn Steel Union has at last solved this problem. It makes practically **one continuous wrought pipe** of the two lengths it joins, because it is itself wrought steel.

The only union in existence that expands and contracts the same as the pipe.

Malleable iron and cast iron unions expand more **slowly** than wrought iron or steel pipe, when heat is applied Malleable iron unions **stretch** under the expanding pressure of the pipe, and because the elastic limit of the metal is low, they **stay** stretched and leak when pipe is cooled

Cast **brass** unions expand more **rapidly** than wrought pipe, and spread away from the pipe under heat, making such joints leak when hot.

Unions made of part malleable iron and part cast brass suffer **internal** trouble every time temperatures change, and leak **in themselves**.

The Mark Union is made wholly from wrought steel, with a soft **drawn brass** seat ring or gasket inserted in the female seat. When this brass gasket expands under heat, it tends to render the joint even tighter It is so soft, and the densified steel male seat that cushions into it is so exceedingly hard, that the Mark Union is proving its ability to hold unprecedented steam and hydraulic pressures under conditions in which every other form of union has failed.

Mark Unions are Sherardized—a process that alloys zinc with the steel This sherardizing is done **after** the threads are cut, protecting **all** surfaces from rust or corrosion.

Mark Unions are stronger than the pipe, because heavier than the pipe, and made of stronger metal than the pipe itself Their superiority in this direction is particularly noteworthy in the larger diameters, where all other unions fall so far short of the proper factor of safety.

For these Reasons and others the Mark Cold Drawn Steel Union is rapidly replacing all other forms of unions for every use where leak-tightness and resistance to corrosion are of value.

A Home Made Alternating Current Motor

¶ Read *Supplement 1688* for a good, clear article by F. E. Ward, E. E., on the making of a one-eighth horse power alternating current motor. The motor can be constructed by anyone of ordinary skill in the use of tools who has access to a screw-cutting lathe with a swing of nine inches or more. The motor is designed to run on the 100 to 120 volt, 60-cycle, single-phase alternating current circuit, now in wide-spread use for the lighting of dwellings The motor will drive a 16-inch brass fan, a small lathe, or a 50-watt dynamo for generating direct current for charging storage batteries, and in fact will do almost any kind of work that can be done by one-man power. Order from your newsdealer or from us.

Of Myriad Uses

Wherever permanence, fireproofness and economy are desired in building construction, Hy-Rib finds a place. Its field of usefulness includes buildings of all types and sizes from residence to skyscraper, from farm silo to industrial plant.

HY-RIB

is a steel sheathing combining in a single unit, lath, studs, reinforcement and forms. Hy-Rib is the ideal reinforcement for concrete, stucco or plaster. To build sidings, partitions, roofs, floors, ceilings, etc., with Hy-Rib is simplicity itself. The easily handled sheets are fastened to the supports and the plaster or concrete is applied. All forms are eliminated.

No matter what you intend to build, you should inform yourself about Hy-Rib. Write for Hy-Rib Handbook—free.

UNDERWOOD
"The Machine You Will Eventually Buy"

Such schools employ hearing night watchmen, as they are more suitable for such work.

Visiting a married mute couple in Brooklyn one day, I inquired how they could tell when their door bell rang so as to respond to it, they having neither dog nor children to hear for them. They showed me a hollow rubber ball suspended from the chandelier in their kitchen, where it could be seen from the parlor and the other rooms in the house. In an ingenious way the ball was attached to the hammer of the door-bell by means of a string, so that whenever the bell rang the hammer would jerk the string and cause the ball to oscillate for some length of time. The swaying of the ball told the busy housewife when someone was at the door. Many families have similar devices. While visiting this same family, the deaf man took me to the foot of his bed. There I found attached to the top bar of the bedstead an alarm clock. "This clock," said he, "awakens me every morning just when I want to get up. I feel the vibration of the alarm quite plainly, as it extends to all parts of the bed."

In the kitchen of another deaf couple living alone in New York city, I found that whenever their door bell rang, an American flag placed in an upright position in front of a window, would fall. When the occupant of the room saw that the flag was down, she or he would know what to do.

A deaf mute doing business in a New York city office has the door bell attached to the electric lamp over his desk in such a manner that the light goes out whenever there is a ring The sudden vanishing of the light causes the busy man to make a quick response.

Anthropological Exploration in Peru

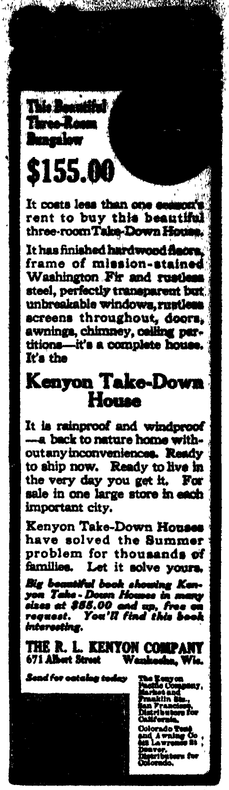
THE Smithsonian Institution has just issued a second report concerning the field work of Dr Ales Hrdlicka of the National Museum, carried on in Peru during the past year, in connection with the Panama-California Exposition at San Diego, for which a very important exhibit in physical anthropology is being prepared. The investigations extended over several hundred miles of the Peruvian coast and over hitherto unexplored regions in the western Cordilleras. The objects of this trip, which occupied the first four months of 1913, were to determine the relations of the ancient Peruvians of the mountains with those of the coast, and to extend the investigations which Dr. Hrdlicka has carried on for many years regarding Indian and especially pre-Columbian pathology dating back about 500 years.

The expedition was a very strenuous one, but proved remarkably successful. Over 100 ancient cemeteries and many ruins, a large percentage of which were previously unknown to science, were examined and over 30 boxes of skulls and other material for future study were collected for the United States National Museum and the Museum at San Diego.

The writer reports that skeletal material, which formerly abounded in Peru, and is essential to scientific research, is fast disappearing, and in a few years cannot be gathered without the expenditure of much time and money.

The results of the expedition will prove of unusual value to anthropology. While some of the links of the chain of evidence are still wanting, it can now be said with certainty that the Peruvian coast from Chiclayo, in the north, to Yauca, in the south—a distance of over 600 miles—was peopled predominantly before the advent of the whites by one and the same physical type of Indian. These Indians were of medium height, with short and broad skulls, and moderately to strongly developed muscles according to the locality. The most important fact ascertained in this connection was that both the Chimu and Nascas, two of the foremost cultural groups of ancient Peru, were identical, and as regards physical characteristics, inseparable parts of this coast people.

According to their location, the people of old Peru were either fishermen or farmers. They seem to have been organized in-



This Beautiful Three-Room Bungalow
$155.00

It costs less than one season's rent to buy this beautiful three-room Take-Down House.

It has finished hardwood floors, frame of mission-stained Washington Fir and rustless steel, perfectly transparent but unbreakable windows, rustless screens throughout, doors, awnings, chimney, ceiling partitions—it's a complete house. It's the

[illegible]

to [illegible] which developed [illegible] greater cultural differences [illegible] environment and other influences.

Some of their smaller dwellings were made of wood, while larger structures were built of small uncut stones, sun-dried brick, or blocks of adobe. Their knowledge of weaving, pottery-making, and decoration was surprising. They wove from native cotton and llama wool, and their designs indicate the changes brought about by time and other influences. The native dress consisted principally of a poncho shirt, a loin cloth, and sandals, with simple head gear.

The pre-Columbian Peruvians of the coast knew the uses of gold, silver and copper, and worked these metals to some extent, especially copper in the manufacture of weapons. Their common weapons were a metal or stone mace, a wooden club, a copper ax and knife, the sling, and in some regions the bow and arrow. Their implements were the whorl, weaving sticks, looms, cactus-spine or bone needle holders, sharpened sticks, copper knives and axes, hoes, and fishing paraphernalia, including nets, sinkers, reed-bundle boats or balsas, and peculiar rafts which were paddled.

Throughout the whole territory along the coast the people deformed the heads of their infants by applying pressure to the forehead, probably by means of bandages and pads, which process flattened the back of the head as well. They did not practice filing, cutting, or chipping the teeth, or other mutilations which would leave marks on the skeletons.

It is interesting to know that these natives seem to have been comparatively free from general bodily ailments before the advent of the white men, although they suffered from several peculiar local diseases affecting the hip-bone, the head, and the ear. The people of the mountains possessed a good, average development of the body and of the skull, and were freer than the coast people from disease. It is evident that in some of the districts serious wounds of the head were frequently followed by the operation known as trepanning, and although this was often crudely done, it was successful in many cases. This practice was probably carried on even after the coming of the Spaniards.

The results of the expedition failed to strengthen the theories of the antiquity of man in Peru, but tended to prove the contrary. Aside from the cemeteries or burial caves of the common coast or mountain people, and their archeological remains, there was no sign of human occupation of these regions. Not a trace suggesting anything older than the well-represented pre-Columbian Indian was found anywhere; and neither the coast nor the mountain population, so far as studied, can be regarded as very ancient in the regions they inhabited. No signs indicated that any group occupied any of the sites for even as long as twenty centuries; nor does it seem that any of these people developed their culture, except in some particulars, in these places.

Dr. Hrdlicka's report is issued in the Smithsonian Miscellaneous Collections, publication 2246, and forms an exceedingly valuable addition to the anthropological works of Peru. It comprises 69 pages of text and 26 plates of illustration, showing specimens collected, locations of the finds and maps of the territory explored.

The Guns of Panama

(Concluded from page 383.)

mounted upon the Crozier type of disappearing carriage, are scarcely less deadly than their larger brothers, or sisters, for guns have been tacitly endowed with feminine appelatives. Although the 14-inch shells weigh but 1,660 pounds, their range is practically that of the sixteens, at extreme fighting range, and they are able to penetrate any armor now in use.

The main defense of a system of sea-coast fortification is found in the mortars. Costing less to manufacture, and projectiles and charges costing less, they are used in great numbers; and the effective range is slightly more than that of the rifles on the disappearing carriages. Fired at extremely high angles, their projectiles invariably plunge directly down upon the target, and though the velocity is comparatively low, no deck armor can withstand them.

The mortars are sunk in pits, in groups of two, each group manned by a company of coast artillery. They are seldom fired singly. As a rule a number of them are directed upon a target and fired simultaneously, a salvo, and in such a hail of steel, directed upon a common objective, at least one projectile, ship-disabling in its power, will most probably strike with deadly effect.

No definite information is given out by the War Department about the number of guns to be in the completed defenses of the Panama Canal, but at such an important point it is reasonable to suppose that it will be ample.

At a rough estimate there will probably be two or more of the 16-inch rifles, from twelve to twenty of the fourteens, and approximately forty mortars, with a large number of the smaller rapid-fire guns

Assuming the maximum, a hostile squadron would be greeted at each discharge of the entire armament with a composite thunderbolt weighing forty tons —forty tons of disabling, death-dealing steel each minute.

The old naval guns of our Spanish-American war period are obsolete. The guns of the civil war class are playthings; and all guns antedating that period of interstate war are as harmless to a modern dreadnought or emplacement, at any range, as the beating of the rain upon the sea.

And fifty years hence our latest perfection that we esteem so deadly will be smiled at in some musty old museum!

Insects in the Upper Air

DR. E. EVERLING of Halle, Germany, is trying to interest aeronauts in making observations of the occurrence of insects at altitudes of several thousand feet above the earth's surface Very few such observations have heretofore been recorded. Dr. Everling himself, in the course of many balloon voyages, has only once noted an insect (a butterfly) at a great altitude. It was, in all probability, carried thither by the strong uprush of air in an incipient thunderstorm, and it may be a general rule that insects do not voluntarily rise above a moderate elevation. Aeronauts are invited to send their observations on this subject to Dr. A. Japha, Zoologisches Institut, Halle a. S., Germany. The meteorological conditions, and especially indications of the presence of strong vertical air-currents, should be noted in connection with all observations.

Meteorological Conference in Scotland.—It is the custom of British meteorologists to hold a breakfast or luncheon in connection with the annual meetings of the British Association for the Advancement of Science. As the Association is to meet this year in Australia, and few meteorologists from Great Britain will be able to attend, arrangements are being made to hold a conference of observers and students of meteorology and allied subjects in Edinburgh early in September.

—thinking of life insurance?

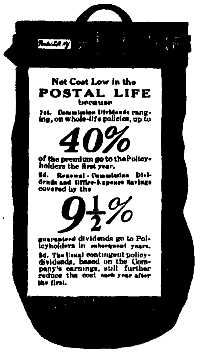
MOST people are; for insurance protection is an **ever-present proposition**: it safeguards the home; takes care of the mortgage; educates the youngsters and provides old age independence.

AGENTS of all the other companies—the 20,000—find it hard to compete with the Postal Life, and it is therefore best not to believe what such agents say about the Company or what they show you in some easily-influenced insurance periodical.

It's on the minds of most people—the thoughtful, humane kind: they're thinking about it good and hard and some 20-000 life-insurance agents are helping them.

The agent, of course, is bent on earning a commission and, incidentally, on beating his last year's record under urgent pressure from his company.

But don't let him do it at **your expense**, for if you take a policy through **any agent, his commission** will come out of **your premium**—the first year and thereafter.



Net Cost Low in the
POSTAL LIFE
because
1st. Commission Dividends ranging, on whole-life policies, up to
40%
of the premium go to the Policyholders the first year.
2d. Renewal-Commission Dividends and Office-Expense Savings covered by the
9½%
guaranteed dividends go to Policyholders in subsequent years.
3d. The Usual contingent policy-dividends, based on the Company's earnings, still further reduce the cost each year after the first.

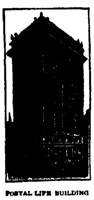
The Postal Life is a highly accredited institution and has the confidence of all thoughtful insurers who take the trouble to find out about it **for themselves.**

They find that the Postal gives **all** that other companies give and **much** that they **do** not or **cannot** give.

For example: the **Postal's Health Bureau performs a most important service in health-conservation by issuing timely Health Bulletins for the benefit of its policyholders and by providing for those who so desire one free medical examination each Year**—a privilege not accorded by any other company. **It will thus be seen that the Postal**

This, of course, will make your insurance cost you more than though you applied **direct** to the **one American company that operates without agents, namely:**

The Postal Life Insurance Company **Saves you Money and Safeguards your Health**



POSTAL LIFE BUILDING

For the reasons here stated and others, the **POSTAL LIFE** is justly designated "The Company of Conservation"—**of money and of health.**

'Twill pay you to find out just what **you** can save on any standard form of policy—Whole-Life, Limited-Payment Life or Endowment.

Just write and say: "Mail full insurance particulars as per advertisement in Scientific American, May 2." And be certain to give **your occupation** and the exact date of **your birth.**

The Company will then send you (*by mail only*) exact figures for your age with the amount of dividends, guaranteed and otherwise, now being paid

No agent will be sent to visit you, the benefit of his commission goes to you because you deal **direct.**

POSTAL LIFE INSURANCE COMPANY
WM R. MALONE, President
35 Nassau Street New York

STRONG POSTAL POINTS

First: *Standard policy-reserves*, now nearly $10,000,000 *Insurance in force nearly* $50,000,000

Second *Old line legal-reserve insurance*—not fraternal or assessment

Third: *Standard policy provisions* approved by the State Insurance Department

Fourth: Operates under *strict State requirements* and subject to the United States Postal Authorities

Fifth *High medical standards* in the selection of risks

Sixth. *Policyholders' Health Bureau* arranges one free medical examination each year, if desired

The Big Expense on Concrete Construction Can Now Be Saved with Self-Sentering

The big expense for concrete forms, the immense dead weight of concrete roofs, have discouraged builders from enjoying the great advantages of this fireproof, enduring construction.

Self-Sentering, the new form of expanded metal, has removed the handicap—the waste time. It has made possible all concrete construction without forms. You can now have floors, ceilings, side walls and roofs built in a fraction of the time required by old methods and at a fraction of the cost. Self-Sentering makes a 2-inch concrete roof or partition—rigid, fireproof, enduring—an economical possibility. Pitched, curved or flat roofs are built with equal facility with Self-Sentering. Self-Sentering has brought about this change because it is both reinforcement and form combined, and your money is spent on *permanent* construction, not wasted on temporary work.

Learn of the Modern Form of Concrete Construction

Write us of your plans and let our advice help you to better, more economical building. Tell us your architect's or builder's name so we can co-operate for your benefit.

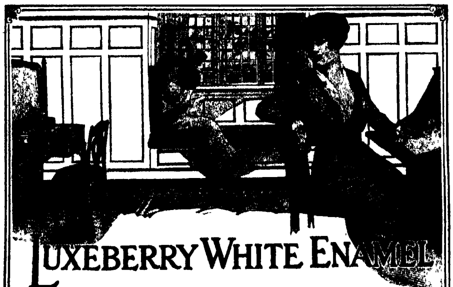
The expanded metal that makes reinforced concrete without forms



To the woman of taste the white enameled room makes a strong appeal. She delights in its atmosphere of cheery, dainty brightness. Not only in her boudoir, bedrooms and bathroom, but in the living rooms as well.

Luxeberry White Enamel produces a rich, deep, snow-white effect unequaled by any other finish. A Luxeberry surface is smooth, satiny and durable, and may be left either a soft dull, or brilliant as the finest porcelain.

Luxeberry White Enamel won't turn yellow, chip or crack and cleans in a jiffy with soap and water

In snow white rooms the natural wood floors should be protected and beautified by the finest floor varnish. Liquid Granite has all the toughness its name implies and it brings out the beauty of the wood, multiplying its attractiveness. Liquid Granite Floors have a durable elastic surface that withstands the wear of grown-up feet and the romp of playing children—a surface you can wash without fear of turning it white—even boiling water has no harmful effect.

Berry Brothers' Varnish has been the first choice of home owners, architects and decorators for over fifty years. Ask your dealer about them or write us direct for varnish information of special interest to home owners

Notes and Queries

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12981) O. O. B. asks: Can you please advise me if it has been positively proved that the electron theory of electricity, or, in other words, the one-fluid theory, is correct? That is to say, that it has been proved that positive electricity is fixed, while negative alone is movable? A The theory of electrons is firmly believed by most scientists. It probably may be said that it is proved as positively as any theory which may be modified at any time by some new discovery. No theory in science is regarded as absolutely proved. A theory is a statement which covers the phenomena to which it applies better than any other explanation If another better explanation is found, the old will be forced to give way to the new A recent work by J. J. Thomson, "Rays of Positive Electricity," pertains to this topic. We send the book for $1.40 postpaid.

(12982) M. A. G. asks: Will ultra-violet light penetrate ordinary glass, and also "Jena" glass, sufficiently strong enough to make an imprint on a photographic plate after it has passed through the above said glass? All visible light being excluded Some works which I have referred to, state that glass cuts off all ultra-violet light, while others state that nearly all of the ultra-violet light passes through. A. Glass is somewhat transparent to ultra-violet rays. We use a cobalt blue glass, combined with a violet glass colored with manganese, and we can get very good ultra-violet effects. By the use of quartz lenses and prisms we can secure much better effects beyond the violet of the spectrum which is formed. You will find about this in a very interesting book by S. P. Thompson, entitled "Light, Visible and Invisible," price $1.75 postpaid

(12983) E. G. M. asks: 1. In your paper of January 10th, 1914, page 43, you speak of the "daylight-saving fallacy." What is that? A The daylight-saving fallacy is that it makes a difference which hours men work if they only work the usual number of hours in the twenty-four. In some parts of Europe riots have been narrowly averted over this question, when it was proposed to have the men begin at an earlier hour in the morning so as to close the day's work earlier in the afternoon, and have time for the garden or other out-of-door pleasures 2. Would not people surely remain out of doors more, walking, playing, if daylight lasted longer after the day's work was over? I notice in the papers that some city near the dividing line between Eastern and Central time has decided to change to Eastern in order to have more daylight hours in the afternoon. A The sensible solution of the difficulty in keeping standard instead of local time is to change the hours of the day's working time as above rather than to lose the advantages of standard time In some cities where local time is about half an hour fast of standard time the shops and factories start at half past six instead of seven and stop for dinner at half past eleven by standard time. In reality the work begins at seven local time and the dinner is at twelve local time The day's work closes at half past five standard, but at six local time Thus the day is kept by the sun, but the hours are those of standard time. 3. I notice in the article referred to, in question 1: "It is stated that British Columbians now sleep during three hours of daylight in summer." Is this because their northern twilight is longer than ours, or do they get up so late? A Twilight lengthens rapidly in the summer as one goes north In the northern part of British Columbia there is little night in the summer, and men must sleep by daylight if they would get sufficient sleep. In the Arctic regions, men sleep by daylight all the time the sun is above the horizon without setting At Hammerfest there are eleven weeks of continuous daylight in summer, and the people keep the twenty-four hours as we do They open their shops at eight o'clock in the morning and close them at six of the afternoon, and sleep at the same hours as men do farther south but it is daylight all the time.

(12984) G. M. G. asks: A suitable container is completely filled with fresh water and hermetically sealed with the same material and of the same thickness as the walls of said container The temperature of the water is now lowered to such an extent that all the water in the container is frozen. Also kindly inform me of the expanding pressure, in pounds, of freezing water. A. Water cannot freeze unless it can expand The force of its expansion in freezing is the same as that required to compress it from the volume it has as ice to that which it had as water The compressibility of water is about 420 ten-millionths per atmosphere One volume of ice yields 0.9178 volume of water at the freezing point. It will thus require about 140 to 160 tons per square inch to prevent water from freezing, and your container must have this strength See Ganot's "Physics" for data on this point. We can send the book for $5.

(12985) P. A. C. asks: 1. Why are only three images of a point formed when two plane mirrors make an angle of ninety degrees with each other? A. When two mirrors make an angle with each other, there are as many images and the object as the angle is contained in 360 degrees. If the angle is 90 degrees, this number is four; one is the real object and the other three are apparent images. The places of the images are found by the rule that the image in a plane mirror is as far behind the mirror as the object is in front and in the perpendicular to the surface of the mirror drawn from the object. It is easy to draw the mirrors at right angles to each other, and prolong the lines to represent the apparent mirrors behind the real mirrors. Then locate the images by the rule above. 2. Will you tell me how to find, graphically, the number of images formed of a point, when the mirrors make an angle of 45 degrees? A With an angle of 45 degrees the method is the same. There will be eight sections in the circle formed by the mirrors, which are in the space behind the mirrors; in each there will be an image, to be located by the method given above. The images will be on the vertices of an octagon. This construction is the basis for the kaleidoscope.

(12986) F. A. G. asks: 1. Will you be kind enough to tell me if the optic nerve is composed of fibers, each fiber having one of its ends connected to the retina and the other end to the cerebrum? I would like to know if each connects one or more cells of the retina with one or more cells of the brain? A There is no difference between the transmission to the brain of a stimulus leading to sight and one producing any other sensation. The nervous system is the sum total of nerve cells, which are called "neurones" by the psychologist, and these act by conducting impulses from the point where the stimulus is applied to the part which can act upon that stimulus in the proper manner Just how a nerve cell conducts or transmits is not definitely known, but the fact is certain Light falls upon the ends of the neurones of the retina, and these act so that the stimulus affects the other end of the nerve cell which may be quite a distance away, and this remote end transmits the impulse along to other nerve cells, and finally it comes into the mental consciousness. It is not light which is transmitted, any more than it is sound which is transmitted over a telephone wire a thousand miles. The stimulus produces a sensation simply, but we call the sensation "seeing" 2 At the point of focus how is the motion or vibration of light transmitted to the fiber, and how is light reproduced in the mind? A Just what the mechanics of the production of a stimulus is, we cannot say. We have always thought of it as like the wind sweeping over a field of grain The heads bow to the breeze and rise again The vibrations of light are transverse, and so, although infinitesimal, may be able to set into vibration the microscopic fibers of the rods and cones of the retina. The texts of Psychology discuss these matters We can supply Thorndike's for $1.50, and James's for $1.75.

(12987) J. W. says: In the SCIENTIFIC AMERICAN SUPPLEMENT, No. 1985, page 48, January 17th, 1914, there was published a mnemonic in French for the ratio of the circumference of a circle to its diameter to 30 places of decimals, or 30 decimal *pi*. There was a humorous challenge to anyone to construct something of the kind in English. I accept that challenge, and submit the following as the best I can do with such restrictions as are imperative, i. e., each word must be composed of a fixed number of letters I believe that the rhythm will help the words to trip off the tongue fluently and render it easy to memorize.

Now I have a means wherewith to tackle—
3 . 1 4 1 5 9 2 6
every now poser inviting attention. Welcome
5 3 5 8 9 7
solutions may be met, although alas untrue.
9 3 2 3 8 4 6
An artful plan you got, enabling you to measure
2 6 4 3 3 8 3 2 7
quadrants.
9

In repeating these sentences it is convenient to stop at the word "tackle" and commence afresh, as at that point the rhythm changes. Of course, it cannot be expected that mnemonic sentences shall be beautiful models of language, but I must congratulate the composer of the French sentences on the success he has achieved. A question occurs to me, sir, as to whether any mathematician ever uses, or is likely to use, such an alarming mass of figures in his calculations. A. We note your lines for the ratio of circumference to diameter. Several have been sent in, and references to several which were printed in England several years ago. It is never necessary to use the figures of this number to the hundreds of places to which the calculation has been carried. We have employed fifteen figures in large computations in astronomy.

(12988) F. E. M. asks: Are two vertical lines ever parallel, and if so, under what conditions and at what point on the earth's surface? I am asking for absolute facts, and not what we consider to be parallel, such as the walls of a building. A. A vertical line is one which passes from the center of the earth to the zenith of any place. It is perpendicular to the surface of still water. Any other vertical line must, in a strict mathematical sense, make an angle with it, no matter how near it is drawn to it, since the only point in common to the two lines will be the point of their origin, the center of the earth. Two vertical lines near together are sensibly parallel. There is no instrument which could detect any convergence in two vertical lines on the equator, six feet high and one inch apart.

The [illegible] Sandwich

THE [illegible] interest in scientific circles as well as in the ranks of social workers concerning some of the problems of nutrition among the masses is exemplified by current discussions regarding school lunches, institutional dietaries, economical menus for the household, and the cost of living. These are constantly bringing out the fact that diet customs are subject to wide inequalities in character in different parts of the world and in different strata of society; and they further make it clear that food habits are not so fixed as was once supposed, but are varied to meet economic changes and alterations incident to the shifting of population. Rubner has remarked that the scene of the changes witnessed in the nutrition of the masses lies in the cities, the country districts representing the conservative factor and adhering more closely to the dictates of tradition. It is in the cities that the most noticeable of the modern changes in dietary customs, such as the increasing consumption of meat and the introduction of ready-to-eat foods, have first taken hold on greater numbers of individuals. Furthermore, the questions of diet in large institutions almost always need to be solved with reference to the local market conditions.

Max Rubner, the eminent physiologist and hygienist of Berlin, has lately presented some interesting data on one of the many transformations in dietary custom which is peculiarly conspicuous in the cities of Germany. It is the rapidly growing tendency to introduce widely what corresponds in general to the American sandwich (*das belegte Brot*) into the daily food-intake. Anyone who observes carefully the eating habits of workingmen in this country and who has followed the enormous increase in the lunch-counter scheme of dietetics among our own population, must admit that the sandwich is something more than a trivial incident in the nutrition of those who live in populous districts. Physiologically, it involves the supplementing of bread—the common "staff of life"—with considerable fat (butter) and animal protein (meat). The sandwich represents a new step in the evolution of bread-and-butter combinations. Rubner believes that the growing use of the meat-laden sandwich is attributable, in Germany at least, to the increased employment of tea and coffee, which require some substantial adjuvant, and also to the greater consumption of sugar and alcohol. The latter lead to a lowering of the protein of the diet, which is thus equalized by the albuminous sandwich. Added to these factors is the growing tendency, especially among the unmarried classes, to eat outside of the home and to patronize the rapid-service, time-saving, sandwich dispensing restaurants and eating-houses.

The average composition of the sandwich, if we may identify this for the purpose of argument with its German competitor, shows that it differs from plain bread in the predominant addition of fat with some increase in protein. One can attach but little value to the "average" composition of so heterogeneous a group of products as is represented by bread-and-meat mixtures of all varieties. Broadly speaking, the comparison afforded shows that 100 calories are distributed in the different food materials as follows:

	Calories		
	Protein	Fat	Carbohydrate
In bread	11	3	86
In bread and butter..	5	58	37
In meat sandwiches..	15	53	32

The great concentration of nutrients in a small volume in the sandwich at once becomes apparent here. The work of mastication is reduced and the entire make-up of the product encourages rapid eating with its possibly unfavorable consequences.

The sandwich, as here represented, exemplifies a tendency to increase rather than diminish the proportion of food of animal origin in the dietary of man; but aside from the fact that it is instituting a larger participation in the use of meat, and is thus working contrary to what many students of dietetics regard as desirable, this form of food is not as economical as is popularly believed. It is true that a palatable sandwich can be purchased for a few cents. The same proportionate expenditure in the household or in the purchase of a warm meal that deserves the name will procure surprisingly more nutriment, even in the more expensive type of restaurant. It has been calculated, for example, that twenty-five cents will buy:

	Calories		Gm. protein
In a public eating-house	3,990	containing	108
In a good restaurant...	1,990	containing	78
In form of sandwiches..	1,140	containing	30

The sandwich is frequently looked on as the "poor man's lunch" and current practice is tending to increase its use. If it is really desirable to increase the purchasing power of a small daily income so as to augment the part devoted to nutriment, the reform cannot be instituted by pointing to the supposedly inexpensive lunch counter. The boarding house and the home wisely administered on the dietetic side still remain the most economical as well as most rational centers for food reforms.—*Journal of the American Medical Association.*

What Is an Enzyme?

ALTHOUGH everyone realizes that enzymes are without question closely related to the life-processes of the cells, and are in some cases the products of their manufacture, it must still be frankly admitted that we have not yet succeeded in characterizing the so-called ferments as definite chemical substances. In truth, nothing conclusive can be stated as to their constitution, nor can they be classified consistently among any of the familiar groups of organic compounds which have a biologic import. Enzymes, in the past, have frequently been assigned to the category of proteins. The reason for this has been that the fermentative properties of certain solutions have usually been associated with the protein fractions contained therein. With respect to their behavior in precipitation, dialysis, alteration by heat, and other properties, the analogy between proteins and enzymes has appeared to be close; so that, pending the extension of knowledge with respect to the chemistry of proteins, some excuse was present for identifying the enzymes as protein in make-up. The enzymes are undoubtedly colloidal in character; and in order to isolate them in greater purity the methods commonly applied to other colloids have been used. The fact that many "purified" enzymes give protein reactions may merely mean that the albuminous material is dragged along mechanically in attempting to isolate the enzymes. Most of the methods for the preparation of them have been such as to justify this assumption. Ohta has succeeded in getting evidence of vigorous enzymatic activity in preparations that are actually free from protein. By digesting commercial emulsin—the enzyme which acts on glucosids like amygdalin—with pancreatic extracts, he has digested away the protein ordinarily found in the crude preparations on the market and has completely removed the proteolytic products by dialysis. The purified emulsin thus prepared was entirely devoid of protein, yet showed the typical hydrolytic action on amygdalin and salicin vigorously. The supposed protein attributes of enzymes must, accordingly, be abandoned.—*Journal of the American Medical Association.*

The Forests of Switzerland covered 2,001,000 acres, or 20.2 per cent of the total area of the country, in 1894, while in 1911 the forest acreage was 2,258,000, or 21.86 per cent of the whole country; an increase of 167,000 acres. Forest conservation is an even more important question in Switzerland than in most countries, because the forests serve as the only protection against avalanches and landslides, which often destroy whole villages. Only small tracts of forests are denuded at one time, and are immediately replanted. The timber is usually cut by contract with individuals and corporations at a fixed price per acre, which includes clearing the land and replanting the trees.

Every time you see a clerk footing bills you can now say:

"There is a man wasting time.

"Whose fault?"

THE Remington Adding and Subtracting Typewriter—a complete correspondence typewriter—automatically totals bills and statements *while it types them.*

Not a moment is wasted on footing or proving

This machine saves 20% to 70% of the time spent on billing.

It is now used by banks, offices and stores, large and small, everywhere.

Sooner or later the adding and subtracting typewriter will be saving time in every live billing department.

When the machine is needed for ordinary letter-writing your stenographer merely touches a lever Instantly—*automatically*—it is made ready for correspondence work.

Whether or not you now see the direct applicability of the Remington Adding & Subtracting Typewriter to your particular business, it will pay you to send for our new illustrated folder—"The Story of a Day's Work"

A few words to your stenographer *now* will put you in the way to receive a copy of this really valuable folder by return mail, will enable you to investigate—*conveniently and without cost*—the saving efficiency of this machine of composite usefulness to every employer of clerical or stenographic help.

Delayed investigation simply means prolonged time-waste and error risk. So while the matter is in your mind send *today* for "The Story of a Day's Work" and learn how profit-reducing elements may be eliminated from your business.

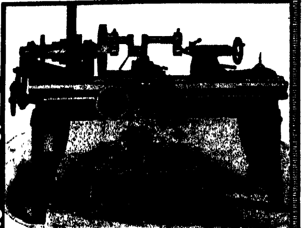
Blacksmiths, Machinists, Garage Owners and Manufacturers in ALL Lines

Get Our Price On The Size and Style Lathe You Want!

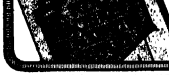
LET SEARS, ROEBUCK AND CO. SAVE YOU $25.00 TO $150.00

We offer a complete line of screw cutting engine lathes (with countershaft or foot power) for every kind of work in manufacturing plants or repair shops Our "Expert" Lathes are accurate in design, heavy, rigid and powerful Our prices are unequaled. Quality for quality, we guarantee a saving of $25.00 to $150 00.



41 SIZES AND LENGTHS Shown in This Free Catalog

It is impossible for us to describe any one of our lathes in this limited space. Our new Machinery Catalog illustrates and completely describes all our lathes, all sizes, all prices, so you can select the one you want and compare the values we offer with those offered by others. Read in our catalog what actual users say



Don't Pay a Penny More

To give you a hint of the money we save you, note the following prices:

9-inch Lathes, $63.00 | 12-inch Lathes, $100.00
10-inch Lathes, 68.00 | 13-inch Lathes, 125.00
11-inch Lathes, 88.00 | 16-inch Lathes, 252.00
18-inch Lathes, $305.00

Write for This Catalog Now!

Whether you need a lathe now or not, send for this book to guide you when you are ready. You can have 30 days' trial of any "Expert" Lathe and you are always protected against defective material or workmanship by our world famous guarantee of "Perfect Satisfaction Always or Money Back Any Time." Our book also illustrates and describes our complete line of other machinery—drills, saws, chucks, mortising machines, factory supplies, screws, bolts, belts, shafting, forges, metal workers' tools, carpenters' tools, grindstones, etc Write postal or letter now Please request "Machinery Catalog No. 7033A."

Lowe Brothers Mill White

is exceptional in working, hiding and wearing qualities

You'll save money and get more satisfactory results in the use of Lowe Brothers Mill White. Not that it's cheaper. It may cost more per gallon, but its working and hiding qualities are so excellent, and it gives such a very long wear, that it's a big money-saver in the end. Lowe Brothers Mill White is washable, easy to keep clean, and after a long wear it leaves a good surface for repainting.

A lot of good brains was used in designing the Delco factory—one evidence is the wealth of window space—another evidence is, that every ray of light that goes into these windows is reflected and radiated from beautiful and sanitary walls and ceilings, covered with Lowe Brothers Mill White.

Lowe Brothers Mill White is *especially designed* for its purpose Just one coat will do wonders toward hiding dark and light-killing walls and ceilings.

Supplied in a handsome gloss finish or lustreless flat finish as preferred, in pails and barrels.

Send this coupon for painting advice

Get the facts

Send the coupon for our booklet about Lowe Brothers Mill White and give us on the coupon an approximate idea of the number of square feet you contemplate painting, also condition of the wall We'll give you an idea of the quantity of Mill White needed and advise whether more than one coat should be used.

NEW BOOKS, ETC.

Evolution by Co-operation. A Study in Bio-Economics. By Hermann Reinheimer. New York: E. P. Dutton & Co., 1913. 12mo.; 200 pp. Price, $1.25 net.

Huxley foresaw that later generations would accept the main doctrines of Darwinism "with as little reflection, and it may be with as little justification, as so many of our contemporaries rejected them." The work under review examines those doctrines in the light of modern research and demurs to the Darwinian position that battle, famine and death directly contribute to the production of higher types. A much more important factor, the author holds, is co-operative activity, with the dietetic and digestive modifications that accompany it. His views on natural and unnatural pabulum, and on digestive transformation, are extremely interesting, and are worthy of further development. It is not necessary for us to accept his low estimate of the Darwinian plane of investigation in order to appreciate his marshaling of what we prefer to call complementary rather than opposing facts. It is regrettable that the style of the work is rather more difficult than it need have been, but its nuggets are well worth digging for.

Electric Toy Making for Amateurs. By T. O'Connor Sloane, A.M., E.M., Ph.D. New York: The Norman W. Henley Publishing Company, 1914. 12mo.; 210 pp.; illustrated. Price, $1.

Under Prof. Sloane's cheerful instruction our boys may spend many happy hours at home in making and operating electrical apparatus and toys. The materials are inexpensive—the despised tomato can will serve for a battery—and the knowledge imparted by such a hobby never fails to prove useful in maturer years. Among the toys dealt with are the electrical dancer, the magic drum and electrical insects, while the more useful appliances and processes dispute precedence with the toys.

The Graphic Arts and Crafts Year Book. American Annual Review of the Printing and Allied Industries. Walter L. Tobey, Editor. Hamilton, Ohio: Graphic Arts Press, 1914.

The progress of the graphic arts in America is here embodied in a format of striking beauty and dignity The illustrations are eloquent examples of the perfection to which our manufacturers and craftsmen have attained. Types, papers, inks, equipment, processes, have all harmoniously advanced together, and the result is epitomized in the impressive reproductions of the Year Book. Processes are shown in their successive stages, page after page of color enlivens the instructive articles—and the letterpress, by the way, is in true artistic balance with the illustration and binding. There is an advertising review and critique by Marquis Regan, valuable papers on engraving and typography, descriptions of the modern pressroom and bindery, and a word on office and plant efficiency A study of the types, papers and setups exhibited in the volume would be of the greatest advantage to manufacturers, advertisers and commercial printers

The Truth About the "Titanic." By Colonel Archibald Gracie. New York: Mitchell Kennerley, 1913. 8vo.; 330 pp.; 16 illustrations. Price, $1.25 net.

This personal narrative, once started, is as difficult to lay down as a "best seller." Naturally, it adds nothing of scientific and practical value to what was brought out in the official investigations, but as a monument to Anglo-Saxon chivalry and bravery it is almost unique. Col Gracie went down with the ship, and only after an under-water swim of incredible duration was he able to climb upon the bottom of an overturned boat That his head was clear and his faculties alert, even in the moments of his greatest danger and physical strain, is a fact for which we should be grateful, since it has contributed to the sharp detail of his simple, manly account. We seem actually to share the long sufferings of the night until the black, menacing bergs take on robes of light with the same sunrise that brings the "Carpathia," like the incarnation of answered prayer, into view of the open boats and their frozen freight. An excellent feature of the work is comprised in the abstracts from the American and British Courts of Inquiry, which form an admirable supplement to the personal narrative Col Gracie died eight months after the disaster, his death being due to, or at least greatly hastened by, the experiences of that night of terror.

Bees and Wasps. By Oswald H. Latter, Senior Science Master at Charter House and formerly Tutor of Keble College, Oxford. Cambridge: The University Press. New York: G. P. Putnam's Sons.

Although this book is confined to British species of Hymenoptera, it can be read with profit by American readers; for it discusses in a simple way fossores or digger wasps, diploptera (double-winged wasps) bees (anthophila) long-tongued bees (Aphidæ) and the social bees. Most interesting is the description of the structural features, namely, of the sting and the tongue.

Floods and Levees of the Mississippi River. By Benjamin G. Humphreys, Member of Congress from Mississippi. Washington, D. C., 1914. 8vo.; 349 pp.

The congressman from Mississippi advocates the levee system for the control of floods, his work having particular reference to proposed legislation. He urges that the disasters affecting the valley of our great central artery of trade constitute national problems of vital importance.

When You Entertain—?

The thoughtful hostess—the host who knows—have both learned that the appointments of the home leave much to be desired if they do not include a silent-flushing closet. The SI-WEL-CLO Closet is known as the closet that does not embarrass because its flushing cannot be heard outside its immediate environment. It is made of beautiful vitreous china, pure white all through and impervious to acids and dirt.

"Bathrooms of Character"

This booklet S-21 sent on request to those who wish suggestions on building or remodeling a home.

With this free book we will [illegible] over one hundred fifty business [illegible] the retail store's library. [illegible]
Economist Training School [illegible]

The history of the levee system is sketched, the [illegible] for Federal aid is chronicled and the relation of the levee system to interstate commerce is strikingly set forth. The control of the river has an important bearing upon the financial success of the Panama Canal, for upon it hinges the production of cotton and the foreign cotton trade. The world-wide evidence indicates the preponderating benefits in favor of an adequate levee system, and the opponents of revetment appropriation would do well to familiarize themselves with the facts set forth in Mr. Humphreys' volume.

Chemistry in America. By Edgar F. Smith, Blanchard Professor of Chemistry, University of Pennsylvania. New York: D. Appleton & Co., 1914.

Material on the development of chemistry in America is so scanty and so widely scattered that in gathering together much of it in this volume, Prof. Smith has performed a service which deserves the gratitude of every true student of American science The chemists who play a prominent part in the book are Robert Hare, James Woodhouse, Joseph Priestley, Thomas Cooper, John MacLean, Samuel L Mitchill, Benjamin Silliman, James C. Booth, T Sterry Hunt, J Lawrence Smith, Wolcott Gibbs, M. Carey Lea, J. Parsons Cooke, and J. Willard Gibbs. Prof. Smith has not made any effort critically to appraise the work of men who have made their mark in American chemistry. He has contented himself with presenting a very trustworthy and painstaking account of what they accomplished rather in the form of a chronicle. We wish that the work of J. Willard Gibbs, by far the most distinguished figure in the history of American chemistry, had been more fully dilated upon

The Evil Eye, Thanatology, and Other Essays. By Roswell Park. Boston: Richard G. Badger, 1913.

This book might well have been called "Studies in Human Stupidity." One reads the author's entertaining and instructive essays on the evil eye, thanatology, serpentism and serpent worship, the evolution of the surgeon from the barber, with a feeling that in this enlightened twentieth century we too may be committing blunders that will furnish interesting historical material for some satiric writer two centuries hence Dr Park seems to have done his work thoroughly and painstakingly.

Les Aveugles. Par Docteur André Curtil. Lyon: Henri Georg, Editeur, 1913.

French literary reviewers have hailed Dr. Curtil as a new Maeterlinck, and well they may His book, a wonderfully sympathetic and poetic production, is a veritable prose poem in its way Written by a scientific man whose professional life has been spent in an ophthalmologic clinic, a man who knows the blind as only they know themselves, the volume must be regarded as a great piece of literature. Particularly striking is its appealing and admirably written psychological study of the blind. Only a man touched to the very heart could have written that most pathetic portion of this book which deals with the efforts of the blind to grasp the meaning of the outer world with what senses they still have, but deprived of the most valuable of all organs

Electricity in Locomotion. By Adam G. Whyte. Cambridge: The University Press. New York: G. P. Putnam's Sons.

This book pre-supposes nothing but the most elementary knowledge of electricity, although it does contain a certain amount of technical description. It, therefore, lends itself particularly well for popular reading

Who's Who in Science. International. 1914. Edited by H. H. Stephenson. New York: The Macmillan Company, 1914.

"Who's Who in Science" has now reached its third year The experience gained in publishing the two previous editions has evidently been most profitable, for not only are nine thousand scientists listed, but much valuable information on the world's universities and societies is given.

Formulaire du Candidat-Ingénieur. Par Maurice Percheron. Paris: H. Dunod et E. Pinat, 1914.

A vest-pocket compilation of definitions, classifications, tables and formulas, with a few blank leaves for written memoranda Geometry, trigonometry, the calculus, algebra, physics and chemistry each have their tiny section. Space has even been found for a few miniature diagrams

Exporters' Encyclopaedia. Tenth (1914) Edition. Containing full and authentic information relative to shipments for every country in the world. New York: Exporters' Encyclopaedia Company. 8vo.; 1136 pp. Price, including monthly corrections and the "Exporters' Review" for the calendar year, $7.50.

Those who have known the advantages of using as a desk guide previous editions of this work hardly need to be assured that in its tenth edition the same high standard of comprehensiveness and accuracy has been maintained. Among its hundred subjects are included lists of steamship lines, American consulates abroad, the countries of the world, banks and bankers in foreign trade, custom house brokers and export commission houses. There is valuable and immediately accessible information on such subjects as foreign currency, cable rates, consignments, consular regulations, financing of exports and forwarding concerns. The area, population, commerce and products of foreign countries are stated concisely The letterpress is interspersed with blank pages, on which the corrections received from month to month may be noted.
